of the inflammatory edema may regain their function during this time. Whether the paralysis of a muscle is due to a destruction or only to an edema of the ganglion cells can be recognized only from the duration of the paralysis. It is therefore important that, after the disappearance of the acute manifestations, the paralyzed muscles receive the right kind of treatment. The author thinks that the effect of galvanization has been overestimated, that in fact it is unnecessary, and that massage and muscular exercise are a better stimulus for the muscles than electricity. However, in resorting to these treatments, measures must be taken to prevent overextension, for, if this is not done, reparation may fail and contractures may develop instead. The contractures result from a disturbance in the muscular equilibrium and in turn cause overextension, which prevents repair of the musculature even if the ganglion cell has become normal again. A paralyzed muscle must be kept relaxed or at least protected against overextension until time (in poliomyelitis about two years) has shown whether the paralysis is a permanent one. The same applies also to paralyses caused by other disturbances: by obstetric trauma, injury, suture of a nerve, neuritis, myelitis and so on. At any rate, the treatment of a paralysis without the proper care for the relaxation of the impaired muscles is a grave mistake. The author shows that overextended muscles can be made to function by removing the contractures. He cites cases in which favorable functional results were obtained after ten years or even longer. He describes in detail one case in which osteotomy of the right foot, tenotomy of the plantar fascia and lengthening of the achilles tendon with a subsequent plaster-of-paris cast resulted in considerable improvement of the function of muscles that for thirty-seven years had appeared to be paralyzed.

Syphilis of Central Nervous System.—Riebeling emphasizes that malariotherapy is the best method in dementia paralytica that has not been treated as yet, and he considers it wrong to use any other treatment. However, when a repetition of the fever therapy becomes necessary, the choice of treatment is debatable. In discussing the aspects of the cerebrospinal fluid of untreated dementia paralytica the author points out that in the present status of serology it is no longer enough to know that the Wassermann reaction is positive. If the inactivated cerebrospinal fluid does not contain Wassermann reagins, the diagnosis of dementia paralytica must be doubted. The cell count is between 20 and 100, but an increase in cells without other changes is of no value for the diagnosis. An increase in the protein content is characteristic for dementia paralytica, but it should not be overlooked that the protein test may be negative in spite of an increase in globulin. The precipitation of colloids (colloidal gold or mastic) is especially characteristic of dementia paralytica. After stressing that it is advisable to study the different protein fractions and their relations to one another in the cerebrospinal fluid of patients with dementia paralytica, the author points out that after fever therapy the cerebrospinal fluid may present widely varying pictures. He thinks that, if the fluid has a normal number of cells, a negative Wassermann reaction and only a slight increase in the globulin content and, if the colloid curves have become flatter, renewed treatment is not necessary for some time but that it is necessary to keep these patients under constant control. He admits that the improvement of the paralytic patient does not run parallel with the changes in the cerebrospinal fluid, but he shows that the repeated examination of the cerebrospinal fluid is helpful in determining the prognosis and that it is a great aid in deciding whether specific treatment should be repeated. He emphasizes that following unsuccessful malariotherapy a repetition is not only unnecessary but should be avoided.

Surgical Treatment of Chronic Icterus.—According to Denk, the dangers of an operative intervention in chronic icterus are frequently overestimated. He reports his observations in sixty-one cases in which operation was resorted to. He shows that, if the necessary precautions are taken, the surgical risk is not sufficient to justify undue postponement in the hope for a spontaneous recovery. Many surgical failures are caused by complications of the lithiasis, which could have been avoided if the intervention had taken place earlier. In evaluating the measures that aim at the reduction of the operative risk, the author stresses blood transfusion as an excellent prophylactic and therapeutic measure against cholemic hemorrhage. To counteract the retardation of blood coagulation, he recommends the administration of calcium salts. The greatest risk involved in the operation is the complete failure of the hepatic function, because it cannot be counteracted as successfully as the hemorrhagic tendency. Nevertheless, the administration of large amounts of fluid, of dextrose and of insulin will aid the function of the liver sufficiently to prevent its complete failure, provided, of course, the damage has not advanced too far. The form of the anesthesia is likewise of vital importance for the success of the treatment. Chloroform and tribrom-ethanol must be dispensed with at all costs and ether should be used only if absolutely necessary, and then very sparingly. In slender persons the intervention may be made by local and splanchnic anesthesia, and in sensitive corpulent patients nitrous oxide anesthesia is the method of choice, particularly in combination with local anesthesia, because it has no unfavorable effect on the liver. The intervention itself should, if possible, be limited to the removal of the obstruction, to the discharge of the bile. The small, contracted gallbladder should be left alone if possible. If it still contains calculi, they should be removed by cholecystotomy, but not before the completion of the intervention on the choledochus. The choledochotomy is done in the transverse direction, if possible, directly over the calculus or slightly above it. Before completion of the intervention on the choledochus, the papilla should be explored and dilated. If exploration of the papilla proves impossible, the duodenum must be opened and the papilla inspected. It is advisable to avoid external drainage of the choledochus.

Paracolon Bacilli in Enteral Diseases of Children.—Hassmann and Herzmann consider paracolon bacilli the atypical colon strains that do not ferment lactose. They found such bacilli in the stools of a large number of nurslings and children with enteral disturbances, during the disorder and frequently also a short while after. Relapsing intestinal disturbances concurred with the presence of paracolon bacilli in the stools. These observations and the demonstration of paracolon bacilli in the punctate of the small intestine in toxic cases seem to demonstrate the etiologic significance of paracolon bacilli for enteral disturbances. Continuous transplantation of the para-

colon strains proved that after a shorter or longer period they changed back into ordinary colon strains. The paracolon strains generally retained their characteristics the longer, the more severe the enteral disturbances caused thereby. On the other hand, studies on ordinary colon strains revealed that they may change into paracolon strains. It may be assumed that such variations develop likewise in the intestine and that they are etiologic factors in enteral disturbances. Paracolon strains may also serve as transfer agents for ectogenous infections. Colon strains that have undergone changes in the intestines of children with enteral diseases may be a source of infection for healthy children. The intracutaneous injection of sterile filtrates of paracolon cultures produced strong local reactions in guinea-pigs and in children. As a rule, the severity of the reactions was related to that of the enteral disturbance from which the paracolon strains had been derived. Filtrates from ordinary colon strains, which had been obtained by successive inoculations of paracolon strains or occurred together with them, caused no reactions or much weaker ones. The etiologic significance of paracolon bacilli in enteral disturbances is proved further by the results of agglutination tests, which, moreover, disclose relations of the paracolon group to the typhoid and paratyphoid groups.

Mode of Action of Apple and Banana Diet.—Baumann and Forschner-Böke show that, although the favorable influence of the apple and banana diet on diarrheal disturbances has been definitely established, the mode of action is still in dispute. Investigations on the latter problem convinced them that the pectins, particularly because of their great swelling capacity, are the most important therapeutic factor. They observed that the swollen, voluminous intestinal contents present in the case of the apple and banana diet stimulate the peristalsis and accelerate the passage, and thus counteract the stagnation of the ingesta, which results from the diarrhea. By the administration of pure pectins, it could be shown that they increase the peristalsis and also have an absorptive action. The fact that the diet provides almost exclusively carbohydrates and that it is practically free from fats and proteins should likewise not be overlooked. The acidification of the gastric contents by the malic acid may be of some influence in that it increases the bactericidal effects; but that this factor is only of minor influence was proved by experiments with neutralized apple and banana diets. The tannin contained in apples and bananas is likewise of only minor significance. That the buffer action of the pectins plays only a minor part in the therapeutic action of apple and banana diets was proved by buffer curves. The authors further report studies on the stools in the apple and banana diet. They determined the pH , the buffering, the water, fat and mineral contents and the organic acids, and they discuss the results of these tests. They conclude that in older nurslings and in young children the banana diet gives better results than the apple diet.

Antianemic Action of Copper.—Rohland induced anemia in rats by a milk diet and then used them for the study of the antianemic action of copper. His studies corroborated that the addition of copper induces a more rapid action of the iron therapy. On the basis of studies on the action of monovalent and bivalent copper, he concludes that the efficacy of monovalent copper is not inferior to that of bivalent copper, and that the difference between these two types of copper is not as fundamental as that between the two types of iron. In cases with low hemoglobin content, monovalent copper seems to surpass bivalent copper, while following the increase in hemoglobin, the efficacy of the two types runs parallel.

*Hereditary Angiomatosis (Osler's Disease) in Two Danish Families. A. Yde and M. Olesen.—p. 1010.

*Prognosis in Massive Hemorrhages from Ulcers. T. Christiansen.—p. 1023.

Hereditary Angiomatosis in Two Danish Families.—Study of five generations of these families shows that the ratio between the members free from hereditary angiomatosis and those afflicted with it is 55:20. Yde and Olesen conclude that the disorder here apparently depends on a dominant factor.

They say that only the treatment of the anemia gives satisfactory results in this disease; reduced iron is effective and blood transfusion is given in marked cases. Universal therapy is of problematic value. Local treatment is directed partly to immediate hemostasis and partly to the greatest possible protection of the patient against further traumas to the angiomata. On the whole, the patients must be advised to abstain from marked exertion of any kind.

Prognosis in Massive Hemorrhage from Ulcers.—Christiansen's material consists of 289 cases of massive hemorrhages ascribed to gastric or duodenal ulcers, 211 of the patients being men. Purely medicodietetic treatment was given. Twenty-five, or 7.9 per cent, died, the mortality for women being 10.3 per cent and for men 7.1 per cent. In the first group, the patients having hemorrhages for the first time, the mortality was 8.9 per cent and for the second group, those having a recurrence, 5.9 per cent. In the sixteen cases in which necropsy was done, gastric or duodenal ulcers were established. Of the 289 patients 203, or 70.3 per cent, were in the first group; the remaining eighty-six had previously had one or more massive hemorrhages. Positive roentgenologic results were found in 101 of 167 patients, or 60.8 per cent. Ewald's test meal, given to seventy patients after the treatment was ended, showed hypersecretion and hyperacidity in 58.6 per cent. The ages of the patients in the first group ranged from 12 to 82, the maximum being between 30 and 40. For both groups the mortality rises considerably after 40, while recurrence as such does not seem to aggravate the prognosis. The prognosis seems to be better in cases in which the hemorrhage is the first and only symptom of ulcer than in those in which there have been symptoms of ulcers, but the duration of the ulcer symptoms apparently plays a subordinate part. The authors confirm that the prognosis seems to be poorer in recent years than formerly, and they are unable to explain this satisfactorily. Their material affords no evidence of periodicity in the frequency of the hemorrhages.

*Tumor of Spinal Cord Treated Operatively and Presenting Inversion of Radius Reflex and Paralysis of Facialis: Case, Vera Johnsson.—p. 625.

Inversion of Radius Reflex and Paralysis of Facial Nerve.—Johnsson calls attention to the occurrence of symptoms from the cranial nerves in cervical tumors. In her case in a woman, aged 39, the diagnosis was hour glass tumor passing through the intravertebral foramen between the third and fourth vertebrae. There were only slight signs of injury to the central nervous system. As operation showed considerable compression of the spinal cord by the tumor, the absence of pyramidal symptoms from the lower extremities is regarded as noteworthy. After the operation the neurologic symptoms were accentuated and a number of new symptoms appeared, including inversion of the radius reflex and facial paresis. The only report on facial paresis in cervical tumors found by the author in the literature was that of Kraus and Silberman, in which two earlier cases are cited and seven personal cases of cervical tumors with paralysis of the lower part of the facial nerve are reported.

THE IMMUNOLOGIC ASPECTS OF GONOCOCCIC INFECTION

P. S. PELOUZE, M.D.
PHILADELPHIA

No one would deny that the interest in gonococcic infections is greater today than at any time since the epoch making work of such men as Finger, Neisser and Bumm focused medical attention on this disease as it never had been centered before. They started the march of progress along scientific lines that soon were abandoned to a great degree when physicians began to search for drugs to kill gonococci. This long quest for bactericides that would penetrate tissue and kill gonococci had a definite tendency to narrow the field of vision until one thought almost solely in terms of gonococci and chemicals with which to kill them. But most of this is changed now and physicians are thinking largely in terms of patients and gonococci, with bactericidal dreams far in the background. Assuredly it is in this direction that progress lies.

With such a salutary change in view, it is of extreme importance that a careful analysis be made of those features of gonococcic infections that lend themselves to a classification under the general heading of immunologic aspects; for it is obvious that this disease does not differ in its broader features from those other acute infectious diseases that are dependent for cure on the patient's ability to develop an immunity to them. Each of these diseases has its own peculiarities, but it is questionable whether the immunity responses of any of them are so varied and so easily put in abeyance as are those of gonorrhea. And it is largely because physicians have not sensed these factors fully that results in the treatment of this disease often have been so lacking in brilliance.

The space allowed for the present discussion definitely limits the scope of it and urges the use of direct and seemingly dogmatic statements. It, however, is to be remembered that many of these are based on clinical observation, and some of them are urgently in need of laboratory proof. They are given because they apparently are in accord not only with the underlying principles of gonococcic infections but also with scientific knowledge of infections in general so far as these may be applied to this disease.

Because of limitation of space, the discussion largely will be confined to the urogenital aspects of gonorrhea. No effort will be made to cover the highly controversial serologic features of this disease aside from venturing

the opinion that they largely are overflow phenomena and not essentially curative ones. In other words, so far as urogenital infection is concerned, I am of the opinion that cure is a local response and not dependent on the development of humoral antibodies. My reason for this belief will develop as the discussion proceeds.

As the matter of tissue susceptibility is one of the most important things in the understanding of this infection, it would be well to lay down some brief near-rules regarding it. In a consideration of these it constantly should be borne in mind that gonorrhea is a disease due to tissue penetration by gonococci; no bacterial penetration, no gonorrhea.

1. Squamous covered surfaces are immune to gonococcic penetration. They may be irritated by gonococcic pus, but when this purulent irritation ceases they regain their former condition.

2. Columnar surfaces are extremely susceptible, are slow with their immunity responses, and are the surfaces wherein chronicity of infection takes place.

3. Transitional-cell surfaces, so far as susceptibility to infection is concerned, must be divided into two classes: (a) those firmly attached to the subjacent structures and (b) those loosely attached. The former are quite susceptible to gonococcic penetration but show rather a ready immunity response as compared with columnar surfaces. The latter are practically immune to gonococcic penetration unless their surfaces are changed by trauma or irritation. Even then they promptly recover if the precipitating nonbacterial factors are removed.

Thus one is almost solely concerned with columnar-cell surfaces and those transitional surfaces that are firmly attached to their subjacent structures. The former comprise the anterior urethra and all the mucous channels and glands emptying into any portion of the canal. In the female one must consider not only the accessory glandular structures but the uterine cervix and the fallopian tubes. Under the transitional-cell surfaces of this class one is concerned with the posterior urethra and trigon in the male and only the trigon in the female. Before puberty in her the vulvovaginal surfaces as well must be included.

Turning from tissue susceptibility to the question of the establishment of immunity response in infected surfaces, one finds a number of things at play. These appropriately might be classed for purposes of description under the headings of physiologic influences and the influences of anatomic structure. The former has to do with those things influencing immunity response by the action of ingested or inhaled substances and by those bringing about an increase of local physiologic activity.

The anatomic classification has to do largely with structural conformation as a deterrent to free drainage.

Physiologic factors center largely around the action of ingested alcohol in checking immunity response (the same action occurs as the result of prolonged inhalation of alcohol or ether fumes) and the influences of the hyperphysiologic states of sexual excitement and menstruation, all of which retard immunity effort to the point of precipitating chronicity of infection. A like influence occurs in some individuals as the result of great physical activity. With the exception of the latter occasional interfering element, removal of the immediately foregoing may be considered as essential if cure is to ensue. Fortunately the only one that cannot be deleted easily from the disease picture is menstruation, which bears much the same relation to gonorrhea in the female as would a monthly alcoholic debauch of several days' duration in the male.

In considering the influences of anatomic conformation on the development of curative responses, one would do well to restrict oneself, for purposes of clarity, to the well behaved male, for he is not subjected to these so-called physiologic insults. Thus the field is narrowed to gonococcic infection as influenced by the drainage possibilities of the structure involved. Before proceeding, however, it is well to bear the following things in mind:

1. Gonorrhea is a purulent infection.
2. The outpouring of pus is due to the irritation of liberated gonococcic endotoxins.
3. The free mucous membranes retain their toxin sensitiveness for great periods of time.
4. When gonotoxin is poured on a free mucous membrane, there is a purulent response within twelve hours.
5. This toxin response, in an individual whose free mucosa has not been actively discharging pus, usually subsides within forty-eight hours.
6. Repeated toxin responses of this sort engender prolonged purulent discharges from even freely draining membranes.

It thus will be seen that, after the acute stage of the disease, the behavior of the free, broad expanses of mucous membrane is largely a mirror of the feeding foci in more poorly draining areas, structures wherein pus remains sufficiently long for bacterial lysis and toxin liberation. This brings me to the possibility of laying down some rather fixed rules regarding the influences of drainage on the possibilities of cure:

1. Good drainage makes for good curative response.
2. Intermittent drainage makes for chronicity of infection.
3. No drainage makes for sterilization of the non-draining structures or, possibly, for abscess formation.

The last may be stated otherwise as follows: If abscess formation does not take place, as usually occurs in compound racemose glands (Cowper's and Bartholin's), a mucous membrane constantly in contact with the same gonorrheal pus for any great period of time undergoes a lytic gonococcic sterilization of both its contents and its wall (epididymides, urethral follicles, seminal vesicles and, in the female, the fallopian tubes).

Just what are the true, underlying biochemical processes that have to do with the destruction of deep tissue gonococci no one knows. That phagocytosis is not the important factor is shown by the fact that it is almost

missing in the deeper mucosal reaches, being confined almost entirely to the interepithelial spaces and the free mucosal surface. That there may be two or more methods is suggested by the fact that tissue sterilization is favored by two seemingly opposite factors, good drainage and no drainage. To go more deeply into these phases of the question, in the present state of knowledge, is to lose oneself in a sea of dreams and conjecture. It is here that research finds its greatest challenge and promises, perhaps, its greatest reward.

Regarding the immunity against gonorrhea, its fixity and its duration, I have gathered throughout the years sufficient data to warrant me in making some rather valuable near-rules that help greatly in understanding many of the seeming vagaries of clinical experiences:

1. There apparently is no fixed immunity to this disease exhibited by the susceptible portions of the urogenital tract.
2. In the presence of the disease a transient immunity is developed against the particular type of gonococci involved.
3. This immunity lasts for from a few months to a year or more.
4. It is not active against gonococci from any other source. In fact, the patient may be infected by these even though he has gonorrhea.
5. If the patient transmits the disease to another, her mucous membranes may change the biologic characteristics of his gonococci so that they may superinfect him.
6. Such a superinfection bears an incubation period equal to a new infection. In this it differs greatly from a toxin response from his own infection, which always appears within twenty-four hours.
7. Repeated infections by the same type of gonococci, as by the repeated transferences between husband and wife, eventually induces a carrier stage wherein the germs live in symbiosis with the host, producing no apparent symptoms.
8. Gonorrhea acquired from a carrier differs in no way from that acquired from one with active evidences of infection.
9. Despite rather general belief to the contrary, it is probable that gonococcic infections, except in carriers, do not lie dormant in sexually active, alcohol consuming males. In other words, they produce symptoms of their presence. They do not sleep for years and suddenly awaken.
10. Virulence of infection is a matter of the soil and not the gonococcus. Patients acquiring the disease from the same individual show all types of gonorrhea from mild to hyperactive.

COMMENT

The question that naturally arises is How can these facts be interpreted into terms of treatment? Well, one makes no mistake by realizing that cure belongs to the patient and helping with the cure belongs to the physician. And, as the patient's own acts easily can nullify the physician's best efforts, it is obvious that the thing of first importance is to gain the former's strict cooperation, to the end that he does not inject into the disease picture those things that check his immunity responses.

Having gained this, one would do well to realize that one must depend for cure on the tissues infected. Thus

one should apply no treatment that could embarrass their curative responses. It is abundantly in evidence that mild mucosal stimulation not too often applied has the power of helping in the process of cure.

As so much of cure depends on the drainage possibilities of the infected areas, one would do well to avoid all types of trauma that possibly could bring about intermittent drainage in the small mucous channels. One also might do well to abandon, under present conditions, the idea of speed, for immunity development is a variable thing in different patients. It seldom is possible to speed it up greatly, and overzealousness commonly eradicates it. To such efforts are to be attributed many of the otherwise avoidable complications.

No mistake would be made in viewing the immunity balance of far too delicate a nature to be played with by the administration of present gonococcus vaccines in large doses. Few things are more easy to demonstrate than that infection may be kept up for long periods of time in this way. My experiences with vaccines in the treatment of infections due to bacteria producing solely endotoxins has been in no sense encouraging. In this disease they apparently overwhelm the patient and prevent him from building up the immunity that otherwise could be expected of him.

Finally, one would do well to study more closely the clinical course of gonorrhea to the end that a more general realization be held of what parts of it are really due to the disease and what parts are due to other factors. For physicians have grown to include in the composite picture of this disease many things that are not really in accord with the immunologic factors at play. Most of these have to do with influences injected by the patient or by some injudicious plan of treatment. Not only has the faulty composite picture engendered an unwarranted skepticism regarding the value of treatment but it has fostered a warranted suspicion of many clinical reports. Far too often are glowing pronouncements made of the value of a certain type of treatment because in the author's mind it improved on his composite picture, when in reality it produced only those results that many gentle plans of treatment give. It is much more scientific to base the value of a type of treatment solely on the improvement it shows in the clinical picture of the disease in gently treated, well behaved patients. To include the roughly treated, poorly behaved patients in the judgment standard is to obtain false values, to mislead oneself and others and to retard scientific progress.

1737 Chestnut Street.

Valgus Feet.—A fairly common factor in the production of valgus feet is a contraction of the posterior muscles of the calf, generally referred to as "short tendo Achillis." The condition is characterized by the inability fully to dorsiflex the foot at the ankle-joint. Normal movement allows the foot to dorsiflex to form an angle of about 75 to 80 degrees with the leg and is essential for normal gait. Short tendo Achillis is not infrequently seen as a "congenital" condition and is quite distinct from spastic paraplegia, in which relaxation can always be obtained with trouble. If the degree of contraction is considerable, the child is forced to walk on his toes. However, with a lesser degree he is able to get the heels to the ground by assuming the valgus position. In adults the contraction is usually acquired; and since it is seen far more frequently in women than in men it is likely to be associated with wearing high heels. . . . When such women wear low-heeled shoes for tennis, etc., their feet are forced into valgus—a common cause of foot-strain and painful calves.—Wiles, Philip: Flat-Foot, *Lancet* 2:1089 (Nov. 17) 1934.

THE TREATMENT OF GONORRHEA

BASED ON LABORATORY OBSERVATIONS DURING THE COURSE OF THE DISEASE

RUSSELL D. HERROLD, M.D.
CHICAGO

Gonorrhea is the one common disease of long known specific etiology in which there is a general lack of uniformity of treatment. This status is partially due to the absence of any outstanding and accepted specific biologic or chemical therapy. It is apparent that those interested in gonococcic infections should compare their experiences and revise their standards according to the consensus obtained from this type of symposium. My series of observations demonstrate again the limitations of local treatment directed to the site of infection. The clinical observations have been made in correlation with repeated stained smears of the urinary shreds, which I have found by routine examination to be an efficient, practical laboratory procedure.

Apparently there are many who have not yet learned that overtreatment is distinctly worse than no treatment. Also, this study emphasizes again that statistical results on the value of new methods of treatment may be misleading if analyzed without due consideration to an efficient criterion of cure. Interpretation of the value of newer methods would seem more accurate if distinction were made between mild and severe types of infection, since these two groups are definitely separated by marked difference of individual response. The mild type, however, may be converted into severe infection by misguided treatment or lack of cooperation by the patient. Therefore, this analysis is given for the purpose of emphasizing some general principles rather than for the advocacy of any specific method of treatment.

One part of this study embraces a series of 100 consecutive male patients with gonorrhea in all stages of the disease. Fifteen patients were not followed, for various reasons, for a sufficient period of time to establish cure by laboratory and clinical tests and therefore were omitted from the statistical summary. This group is considered specifically in relation to local treatment, but the discussion of the adjuvant treatment measures is based on a large number of additional observations that were made previously.

The infection was limited to the anterior urethra in sixty-five patients when first seen, while thirty-five had infection of the posterior urethra and its adnexa at the time of the first examination. Forty-eight patients were cured without extension of the infection into the posterior urethra. It was found that the average time for cure was twenty-seven days, with the shortest period four and the longest seventy days. Twenty-three, or almost half of the patients who were cured without posterior complications, yielded permanent negative shreds between the fifteenth and twenty-fifth days inclusive. Forty-two of these patients had shreds that were consistently negative for gonococci after the original negative was obtained. Six had intermittent positive and negative shreds, but there were no two negatives in succession before they remained consistently negative. An average of ten shred examinations were made from one to four day intervals during the course of infection. Frequently the smears would yield a few

faintly staining diplococci, either intracellular or extracellular, before shreds consistently negative for gonococci appeared. This suggests lysis of the gonococcus as one phase of the immunity response. It has been said that such appearance is likely to follow when cure is effected by adjuvant vaccine therapy. However, since this group of forty-eight patients were not given any specific vaccination, it would seem to indicate that the mechanism of cure is similar and is probably aided by biochemical reaction in either instance. Bacteriologic cure during the anterior infection was confirmed by an average follow-up period of seven and one-half months, varying from one to eighteen months, during which time there was no clinical or laboratory evidence of infection.

PRINCIPLES OF TREATMENT

The routine treatment consisted of a daily anterior "in and out" injection of 1:4,000 dilution of acriflavine hydrochloride similar to the technic described by Boyd,¹ except that two successive applications were made. The treatment was given with the patient on a table. The urethral content is released slowly, and the cotton is applied over the meatus in the upright position. Between five and ten drops of the antiseptic will drain from the urethra when the cotton is removed at the end of the treatment. The use of 2 to 4 cc. with but momentary retention makes it unlikely that any antiseptic is forced into the posterior urethra. Twenty-five of this group received daily injections only at the office during the first two weeks. While a few patients were permitted to give self injections on the days that no office treatment was administered, others were given only office treatment from three to four times a week. An English preparation of acriflavine hydrochloride was used which seems to produce less irritation and compares favorably with the use of other preparations of acriflavine hydrochloride that were made less irritant by incorporation in a gelatin base. It was unusual to notice any evidence of irritation from the use of acriflavine hydrochloride in the described dilution without forced retention once daily for a period of two to three weeks, but after this period its application was made in from 1:6,000 to 1:8,000 dilution alternating with one of the mild silver salts. It was noticed that one injection daily of acriflavine hydrochloride controlled the generalized infection for a period of twenty-four to thirty-six hours where the course of disease was progressively favorable. Evidence of local activity of infection, however, could be noticed after this period. While it is possible that equivalent results might have been obtained without the use of oral medication, the patients in this series were given oil of santal in a dosage of 5 minims (0.3 cc.), from three to four times a day.

Provocative tests consisted of an anterior "in and out" injection of silver nitrate in 1:1,600 dilution followed by a 1:800 dilution and occasionally one as low as 1:400. When sounds or bulbous bougies were used they were inserted only in the anterior urethra after smears proved negative. In a few patients without clinical symptoms and with the inclusion of gonococci in the shred as the only evidence of continued infection, an "in and out" injection of 1:1,600 silver nitrate was frequently tolerated without exacerbation of symptoms and seemed to reduce the period of infectivity. As a whole, the group that were cured during

the anterior stage of infection responded quickly to local medication, and the first urine, if hazy or cloudy on initial examination, changed within a few days to the classification of clear with various degrees of shreds. A previous smaller series of patients compared favorably when silver iodide was used instead of acriflavine hydrochloride. However, two injections daily frequently were required to control the discharge as well as with one daily injection of acriflavine hydrochloride. It may be significant that the silver iodide is precipitated from a concentrated solution of sodium or potassium iodide, and therefore dilutions as used contained about 1 per cent of soluble iodide in association with the suspension of silver iodide. A prostatic examination was made in all patients before they were discharged from observation.

RESULTS OF TREATMENT

The infection in seventeen patients of the first group limited to the anterior urethra on initial examination reacted unfavorably to the treatment described. Six of this group received no local treatment because of hyperacute infection, and the remainder gave poor response to local treatment, which seems to indicate that there is a definite percentage of patients in whom local treatment does not produce benefit, and the oral administration of such sedatives as oil of santal is only of moderate value. This observation seems to indicate clearly a varying degree of individual resistance in the urethra to the gonococcus which may be purely local, or a local manifestation of a generalized antibody response. I noted that ten patients who responded to cure within the shorter period of time had similar mild infections when treated for gonorrhea from three to seven years previously.

Analysis of a total of fifty-two patients with posterior gonorrhea, including thirty-five with deep involvement before the initial examination, was made in correlation with laboratory tests. Here, as in anterior infections, shred smears have proved quite reliable in the determination of infectivity as well as in the evaluation of various therapeutic measures, although there were more intermittent negative and positive smears. There was a greater variety of medication in this group.

In almost every instance in which there was a history that antiseptics had been applied during the subacute stage to the posterior urethra by instrumental instillation, such as the Guyon catheter, shreds seemed to remain positive longer than by other treatment, such as application by anteroposterior injections. At such time when clinical symptoms and urinary examination indicated that posterior applications were advisable, acriflavine hydrochloride from 1:8,000 to 1:10,000 was used first. Later, acriflavine hydrochloride was used alternately with potassium permanganate or mild silver protein preparations.

During the acute posterior infection, with both glasses cloudy or hazy, and with or without acute disturbance of urination, there is general agreement that prostatic manipulation or local medication through the urethra is contraindicated. Sedatives in sufficient dosage to control pain and tenesmus together with heat and rest comprise the principal measures of safety. Oil of santal, which is sedative and mildly gonococidal, was used with some benefit in such infections but is not ideal. In the subacute posterior infection without acute urinary disturbance, and with both glasses cloudy, oral administration would seem to have its greatest useful-

1. Boyd, M. L.: Acute Anterior Gonorrheal Urethritis Cured with Acriflavine, *J. Urol.* 19: 89 (Jan.) 1928.

ness. Also, oral medication may serve as a preliminary test of tolerance before application of medication through the urethra, or to prostatic massage.

Some patients with chronic infection will often show very few shreds in the voided urine after prostatic massage. In this type the prostate is normal in size and has a borderline normal consistency. The first urine is semiclear with shreds from one to four plus, and the second is clear. This seems to indicate that much of the infection is in the posterior urethra and its adjacent pockets and ducts. In this group shred smears proved almost as efficient as in anterior infections. Posterior application of medication preceded prostatic massage. The other group with definite areas of induration in the prostate often associated with periprostatic or perivesicular infiltration seemed to be more safely treated by massage and heat preliminary to posterior medication. Here, three negative shreds were occasionally followed by a positive smear or even clinical exacerbation. As a rule, in this group more pus and purulent shreds could be obtained in expressed secretion, and more recently I have fished the shreds for staining separately from the whole secretion. The microscopic results have been more consistent.

The average period of time until cure after the onset of posterior infection, or after the patient came under observation, was sixty-one days, with the shortest twenty-one days and the longest seven months. The highest percentage of patients were cured between the sixth and the ninth week after the onset of posterior symptoms. The two patients whose duration of infectivity was seven months had arthritic complications. *Gonococcus* antigen seemed to influence favorably the progression to cure of arthritis in each instance. The termination of infectivity, however, was preceded by three months of complete absence of subjective urinary symptoms with prostatitis and a single positive shred as the only clinical evidence of active gonococcal infection. During this time prostatic massage was given alternately with increasing doses of the gonococcus antigen to avoid the possibility of activation of arthritis from too great stimulation. Similarly, many of the other posterior infections showed clinically inactive infections from one to three months associated with positive shreds. I believe that many patients are dismissed or voluntarily discontinue treatment at such a time and proceed to spontaneous cure later. This observation is important from epidemiologic control of the disease, since the patient is certainly infectious and much more likely to expose others than when symptoms are clinically active.

ORAL, INTRAVENOUS AND INTRAMUSCULAR TREATMENT

Many drugs by oral administration have been compared in this study, and in general the results confirm oil of santal as more useful than many others. I have not been greatly impressed by any of the dyes of the selective excretion type as determined by clinical and laboratory evaluation. While a small percentage of patients received some benefit, routine use did not seem justified. Such antiseptics seemed more efficacious in the stage of subacute posterior infection. The influence of the reaction of urine has been considered in relation to the course of infection. In a small series of patients, induced acidification seemed unfavorable during the acute infection. On the other hand, preliminary observations by Ewert and myself have indicated that in

many instances there is more prompt clearing of the urines in subacute and chronic infections when the reaction is in the high alkaline range (above p_H 8.2 or 8.4) than with many of the so-called urinary antiseptics. There is a prompt decrease in the number of shreds as well as an apparent favorable change in their characteristics. We are making a study of the influence of such bacteriostatic urines on the period of infectivity, since the final evaluation must be determined on this basis. At least further observations seem worth while, but confined to subacute and chronic infections until more is known about the tissue reactions to alkalinization which we hope will replace oil of santal.

Many intravenous chemicals have been tried and only calcium gluconate has proved of outstanding value in cases in which its optimum results were obtained during the acute stage of such complications as epididymitis. Afterward, when there are subacute and chronic infiltrations, sodium iodide intravenously may be substituted to advantage. The reports of intravenous therapy for uncomplicated gonorrhea almost universally contain a qualifying statement that results by intravenous methods are more favorable when combined with local medication and treatment of the prostate.

There is no doubt that good but not consistent results have followed the intramuscular injection of foreign proteins. Here, autohemotherapy proved as efficient as other foreign proteins and had the advantage of producing very little or no local reaction. The results have been more consistently favorable in the systemic complications, such as gonococcal arthritis and mild iritis, than in complications adjacent to the urethra. In some instances, however, autohemotherapy seemed to have a favorable preparatory influence on the prostate, so that afterward there was an increased toleration of the prostate to massage.

VARIOUS ANTIGENS

There is still a general disagreement as to the value of vaccines in gonorrhea. There are undoubted favorable results in many instances following the administration of vaccines, but results must be analyzed with due consideration to the type of adjuvant treatment as well as to a marked individual variation to the spontaneous course of infection. I believe there is a majority opinion that, whatever antigen is used, initial injections should be so small that very little local and no general reactions are induced. Increase of dosage should be gradual to avoid the production of complications or decreased resistance at the local areas of infection. Antigens vary largely according to the amount of toxic protein as obtained during their preparation, and hence differences are more quantitative than qualitative. It is not necessary to consider foreign preparations until licensed by the Hygienic Laboratory.

A very potent extract may be obtained by making a heavy suspension of gonococci in physiologic solution of sodium chloride. A preparation known as ecto-antigen has been described by Horder and Ferry and has been recommended because it is said to have a low toxicity associated with a high antigenic content. Pelouze² has reported rather unfavorable results with a bacteriophage preparation in cases in which the local and general reactions undoubtedly were due to its content of toxic gonococcus protein. Several years ago I

2. Pelouze, P. D., and Schofield, F. S.: A Laboratory and Clinical Study of the Bacteriophagic Principle Elaborated by the Gonococci, *J. Urol.* 17: 407 (April) 1927.

did a large amount of work on the products of broth cultures that were highly toxic, but I did not feel that the clinical results were good enough to justify me in recommending this preparation for general use. I have had very little experience with a similar product known as the Corbus-Ferry³ filtrate, but the description of the laboratory and clinical work seems to indicate that the two products are closely allied. My preparation when given in doses leading to moderate to large local reactions sometimes produced certain deleterious focal reactions. These consisted of the precipitation of epididymitis and occasionally arthritis, with apparent activation of the infection in the urethra and its adnexa that seemed partially to paralyze the anti-infective forces. In other individuals there was almost instant and permanent clinical benefit, but unfortunately some of this class persisted in their infectivity as in a carrier state for a long period of time. The illustrations and descriptions of the local reactions by Corbus indicate that his recommendation of initial dosage from 0.5 to 0.75 cc. in chronic infections might produce deleterious reactions similar to those from the broth preparation I have described. He also quotes the work of Clark, Ferry and Steele⁴ in which titrations demonstrated positive skin reactions in dilutions of from 1:1,000 to 1:1,500, which is approximately the same potency as the products on which I⁵ made my investigations after 1926. An earlier product that I⁶ described in 1925 was of less potency, which may have been due to the enrichment of the broth with a high percentage of ascites fluid.

More recently another product has been described which is made by the induction of artificial lysis of young cultures through the agent of bacteriophage, although the end product contains little if any bacteriophage. Skin tests indicate that it is distinctly less toxic than the filtrates of five to seven day broth cultures that I have previously investigated. Recently, Gernon⁷ has reported favorable results in a series of 174 adult male patients. There were strikingly few untoward reactions in his series. It may be of some significance that more than 90 per cent of Gernon's patients did not receive any local treatment. Gernon in comparative tests did not note any advantage of the intracutaneous as compared to the subcutaneous route of administration of the antigen, which conforms also to my experience. It must be remembered that the outstanding examples of the most perfect immunizations that have withstood the test of time, notably in diphtheria and typhoid, have been accomplished by subcutaneous injections of the respective antigen, and in both instances the mucous membranes are the usual atria of infection. Consequently, I believe that conservatism should rule at this time in preference statements for the route of inoculation until a large number of well controlled observations have been made under like conditions. Blatt⁸ and his co-workers have reported favorably also with the same gonococcus lysate in a small series of children with cervicovaginitis.

Investigators of biologic therapy tend to limit adjuvant treatment so that it is sometimes difficult to tell when the benefit of less local treatment ends and vaccine value begins. I believe there are some patients who will react unfavorably to any of the gonococcus antigens described. A second group respond well to vaccines, while a third group with mild infections progress favorably to prompt cures with conservative treatment in the absence of biologic therapy. It is certain that there are many correlative observations needed before vaccine therapy can be recommended in all cases without certain qualifications. While biologic products seem at present to be the most hopeful method for future standardization, the results should be analyzed conservatively with particular consideration to the indications and contraindications in the various stages of gonorrhea, and controlled by careful follow-up periods to define more accurately the termination of infectivity rather than the alleviation of clinical symptoms.

OTHER BACTERIA

Gonococci in smears of shreds are less likely to be associated with other confusing bacteria, and the distinct morphology and arrangement in the pus cells are less apt to lead to errors because of pseudo-intracellular bacteria that result from bacteria being superimposed on leukocytes. Likewise, similar smears from nonspecific prostatitis frequently reveal the infecting organism unmixed with the nonpathogenic flora of urethral smears. The association of colon bacilluria in gonorrhea was suggested by the bacilli in shred smears, which was confirmed by urine cultures in 10 per cent of this series. In several instances more than 90 per cent of the haziness in both glasses proved to be due to the contained growth of colon bacilli. The smears are prepared by fishing the largest shred from the first voided specimen by means of an ordinary platinum or nichrome loop as used in bacteriologic work. A thin smear is made of the shred, which dries promptly and is fixed and stained by the same routine as urethral smears.

Staphylococci are the most common of all other bacteria that must be differentiated from typical gonococci in smears and may be confusing even with a gram stain, since it is well known that gram-negative forms of staphylococci are not unusual. *Micrococcus catarrhalis* does not occur in more than 1 per cent of male patients.

There have been several reports on the dissociation of the gonococcus into atypical forms. Recently, Raven⁹ has reported the accomplishment of changes in vitro from normal to gram-positive types as well as other cultural and microscopic changes with variable staining characteristics, and the polyphasic forms varied from globoid to gram-negative granular bacilli. It is noteworthy that Raven could produce modifications through the action of immune serum. This phenomenon raises the question whether vaccines or the absorption of gonococcus toxin during complications may produce dissociation in vivo, and if so whether it would be a favorable or unfavorable influence on the period of infectivity. I have seen variants develop readily on whole human blood agar and have suspected but not proved the presence of atypical forms in smears, particularly from patients with chronic gonorrhea. Cultures may be advisable as a supplement to smears in the determination of cure in selected instances in which there has been clinical evidence of deep involvement of

the prostate and seminal vesicles. At any rate, caution should be used in making statements of cure when latent periods alternate with activity. Therefore, in the future other and more complicated factors may be introduced into the investigation of gonococcic infection.

SUMMARY AND CONCLUSIONS

One application of an antiseptic daily is sufficient to control mild infections and is more safe than frequent injections.

Severe infections are not suitable for local application of antiseptics, and borderline severe infections should have local treatment discontinued if clinical improvement is not prompt.

Intravenous and intramuscular therapy does not produce a dominating influence on the urethral infection, and such benefit as follows its use is due to a favorable influence on the infected adnexa.

The more recent gonococcus antigens should be applied conservatively until more general agreement permits a recognized standardization.

7 West Madison Street.

THE TREATMENT OF GONORRHEA IN THE FEMALE

EMILY DUNNING BARRINGER, M.D.

NEW YORK

The successful treatment of gonorrhea depends largely on a thorough understanding of the underlying pathologic condition and on making a careful diagnosis before any type of treatment is instituted. The diagnosis should be established by a positive finding of the gonococcus by spread, culture or complement fixation test.

Gonorrhea in the female can be likened in many ways to a typhoid infection. Taken as an acute infection in a woman or girl who has previously had normal pelvic organs, one may expect a fairly definite clinical course in an ascending infection, which passes up above the internal os. Thus it will run its course for a period of six to seven weeks, reach its clinical peak and then begin to subside, so that at the end of twelve to fourteen weeks one may look for a cessation of the clinical symptoms and the organs may return to approximately their original conditions and be free from the gonococci. This is barring complications. But gonorrhea similar to typhoid is prone to complications.

Another factor to be considered is whether the gonococcus is the only offending organism or whether other pyogenic organisms are present which give rise to a so-called mixed infection. It is this admixture of other organisms which is usually found in the complications and especially the prolongation of the complications. Still another factor to be considered is the resistance of the patient, and it is the careful understanding and evaluation of all these various considerations that underlie intelligent treatment of gonorrhea in the female.

Gonorrhoeal cases clinically fall into three groups, acute, subacute and chronic, and the treatment will vary with these different stages.

Thus in the acute stage the main indications are for absolute rest, lack of trauma and treatment directed toward preventing the spread of the infection. Ill advised douching and medication of the cervix in very

acute cases may result in just the outcome one is trying to prevent. It is debatable whether, in these very acute cases, rest in bed, with carefully ordered general medical supervision, and only local cleansing of the external genitalia do not lead to recovery as satisfactorily without local treatment.

However, it is my routine procedure in acute cases in which it is obvious that the infection is ascending to give the patient, in addition to absolute rest and lack of trauma, mild heat in the form of medicated douches under low pressure and the administration of a solution of mild silver protein by gentle application to the cervix and urethra. The greater degree of heat, 130 F. as given by the Elliott machine, seems unwise during the acute stage because of the softening and relaxation of the cervix, thereby opening up one of the natural barriers to the spread of infection.

In the subacute stage the complications are usually found as possible gonorrhoeal infection of the rectum; thus it is not uncommon to have Bartholin or Skene's glands and ducts involved. These in turn will often subside spontaneously in the course of the routine treatment of the infected urethra, and it is better in my judgment not to attempt any local treatment of these glands until expectant treatment has failed. It is in this stage that greater degrees of heat may help, and this may be given by the medicated douche up to 116 to 118 degrees or with the Elliott machine, whereby the heat may be pushed up to 130 degrees.

With the chronic stage it is important to try to estimate what organisms are responsible for the continued symptoms. Occasionally symptoms continue because of a persistent virulent infection by the gonococcus. It is much more likely, however, that the gonococcus has passed out of the picture and that the symptoms are resulting from infection with the streptococcus or actinomyces. If the chronic symptoms are due to the gonococcus, especially perimetritis, continued heat therapy, as prolonged hot douching, Elliott machine treatment, or diathermy, will undoubtedly be effective. If the streptococcus or actinomyces is the offender, probably little will be accomplished.

It is in this stage that one is confronted with complications that have not yielded to expectant treatment and it becomes necessary to consider radical measures.

Thus, intractable Skene's glands should be irrigated with an antiseptic solution through a small malleable tipped needle made for this purpose. If this is not efficacious, the gland should be obliterated by the passage of an electric cautery needle down through the duct.

Periurethral abscess should be treated expectantly by careful massage, the abscess being emptied into the urethra and the sac filled with an irritant antiseptic solution. These should be opened surgically only when this expectant method has failed.

If Bartholin glands do not subside with expectant treatment, careful resection should be done, preferably by the intravaginal route, as described elsewhere.¹

Persistent lesions of the cervix may call for radical treatment. If there are chronic sluggish erosions, it is important to know by culture what organisms are responsible. If, as is often the case, actinomyces is responsible, iodine therapy should be given by mouth and locally.

Read before the Section on Urology at the Eighty-Fifth Annual Session of the American Medical Association, Cleveland, June 13, 1934.

1. Barringer, Emily D.; Williams Anna W., and Wilson, M. A.: Resection of Bartholin's Glands, *New York State J. Med.* 22: 145 (April) 1922.

Careful coagulation or cauterization by the electric needle is often indicated, and in selected cases the conization of the cervix is valuable. But it is always practical to stress again the importance of selecting these cases with greatest care, for an ill advised operation on the cervix of a recent gonococcus patient may stir up a fulminating salpingitis.

Operative intervention on tubes and ovaries infected by the gonococcus should be done only for urgent or definite reasons and should be avoided whenever possible. Spreading gonococcic peritonitis is rare but may be fulminating in character, especially in young girls, in whom it may simulate a ruptured appendix and calls for prompt operation. The perimetritic exudate of the acute and subacute stages may become completely absorbed. The sealed off gonorrheal pyosalpinx soon becomes sterile pus and may subside, and the possible functional return for these damaged organs is not yet fully appreciated.

Can the curative process be hastened and impending complications aborted? Will increase of the antibody formation, as administration of vaccine, accomplish this? There is considerable division of opinion in regard to the efficacy of vaccine therapy. A number of authors, as Bruck, Rohrbach, Schultz, Oppenheim and Verboff, find little value in this form of therapy, while Monzer, Merkurien and Silber approve its use. Demonchy advocates enormous doses of stock or autogenous vaccine and reports satisfactory results. He states that quite a number of cases are cured by a few injections without local treatment. However, the stage of the infection seems to make a difference, for in twenty-five cases of acute gonorrhea in the male treated by the Demonchy vaccine, as reported by Wishengrad, the results were not impressive, as the number of cases cured were small, the time required for cure was longer than the average and there was a tendency to stir up an arthritis, which is a fairly rare symptom.

This possible value of massive dosage was brought to the attention of Dr. William H. Park by reports of

routine spreads, cultures and complement fixation tests were made in correlation with the clinical observations.

TECHNIC OF GIVING VACCINE

The vaccine was given intramuscularly in the deltoid region of the arm. The number of doses given varied from five to twenty-one, with an average number of approximately fifteen. The initial dose was in most cases 3 billion organisms, and each consecutive dose was increased by half the preceding one, if reactions on the part of the patient were not unduly severe. The maximum dose given to any patient was 56 billion organisms. Most patients did not receive higher than 40 billion organisms, as they reacted severely before that point was reached. When reactions were very severe the dosage was reduced and again increased care-

TABLE 2.—Average Time in the Hospital

	Chronic	16 weeks	
Routine.....	Acute	18 weeks	(2 cases, 15 and 22 weeks)
	Subacute	17 weeks	
	Chronic	17 weeks	

fully, or in some cases the vaccine was continued at that particular dose. The interval between each dose was seven days.

Reactions, local and general, occurred in nearly all cases, the severity of which was in general in proportion to the dose, but they varied considerably in discomfort after an 8 billion dose, while others did not complain after 20 billion. As a rule reactions were not severe until the 8 billion mark was passed. General reactions consisted of nausea, vomiting, chills, headache, malaise, elevation of temperature to from 99 to 103 F., and rapid pulse. A few patients complained of pain in the pelvic region. The patient returned to normal as a rule in from twenty-four to forty-eight hours.

Local reactions caused much discomfort and again, allowing for the individual susceptibility of the patient, were in proportion to the dose. They consisted of an area round the site of injection of marked swelling, redness and induration, acutely tender and painful; in other words, a local cellulitis. In some cases, after the larger doses, this area was from 4 to 6 inches in diameter and did not as a rule subside for four or five days.

The gonococcus vaccine was prepared by the New York City Bureau of Laboratories as follows:

The vaccine is prepared of seven of the Torrey strains (5, 8, 15, 32, 34, 41, 42), which represent the known serologic types of gonococci. The stock cultures are kept at body temperature in duplicate sets and are transplanted at regular intervals.

Before the vaccine is prepared, the cultures are plated and examined for purity and for characteristic growth. Special attention is paid to the smoothness of the growth. If there is any tendency to roughness, the cultures are transplanted several times at short intervals, which usually results in a smooth growth.

The cultures are then grown on the surface of North medium in quart Blake bottles for from thirty-six to thirty-eight hours and the growth is washed off with sterile physiologic solution of sodium chloride. The growth of each bottle is examined by smear for purity and then collected by means of sterile pipets into a sterile bottle. A small amount of the vaccine is removed for standardization and the vaccine is heated in a water bath at 55 C. for one hour, in order to kill the bacteria. After heating, the vaccine is tested for sterility

TABLE 1.—Distribution of Cases with Reference to Treatment

	Acute	Subacute	Chronic
Vaccine 3 billion upward.....	2	14	14
Vaccine 3 billion maximum.....	0	2	3
Routine.....	2	9	19

work by Richards, who claimed exceptional results from very large doses of vaccine. Dr. Park suggested that I undertake a study of cases in which large doses of vaccine were given, in contrast with another group of cases on routine treatment to act as a check. After the work was well under way Dr. Park made the suggestion that I put some of my cases on small doses (maximum 3 billion) to see whether the larger doses were more efficacious than the small doses. Unfortunately, owing to various exigencies, I could not have an equal number of cases in each group. I took the cases in sequence and no effort was made to pick cases for either type of treatment.

In this way I had on vaccine therapy thirty cases (3 billion upward) and five cases on small doses (3 billion maximum), and on routine treatment thirty cases.

The cases were further rated as acute, subacute and chronic.

All the cases were hospitalized in the gonorrheal wards of the Kingston Avenue Hospital, and weekly

as follows: A representative amount of the vaccine is inoculated into dextrose broth and on North medium. If any of the organisms survived the heating they will grow on this medium.

After testing for sterility, 0.5 per cent phenol is added to the vaccine as a preservative. The number of organisms in a cubic centimeter of the vaccine is determined by Wright's method. Each lot of vaccine is given a preparation number and the vaccine is labeled with the date of preparation, the concentration of bacteria per cubic centimeter and the preparation number, and the vaccine is placed in the icebox at from 4 to 8 C. This constitutes the concentrated stock vaccine.

The tests for sterility are incubated at body temperature for seven days and if at the end of that time there is no growth the vaccine is considered safe to use. From the stock vaccine further dilutions are made, as required, in sterile physiologic solution of sodium chloride containing 0.25 per cent phenol, and the diluted vaccine is bottled into small vials. After bottling, the finished product is again tested for sterility in the manner described before, and it is only after the final test shows that the vaccine is sterile that it is ready for distribution. Each vial is labeled with the kind of vaccine, the concentration of cocci per cubic centimeter, the preparation number, the lot number of the bottling, the date of preparation, and the date of expiration. The period of potency is eighteen months if the vaccine is kept in the icebox.

In preparing the vaccine every effort is made to use antigenic cultures, to keep the vaccine uncontaminated, and to insure safety in using it by carefully testing it for sterility.

COMPARISON OF THE ACUTE CASES

The number of acute cases is much too small to draw conclusions from. However, the stay of the two acute cases on vaccine therapy in the hospital was actually shorter than the routine cases, vaccine cases averaging thirteen weeks and the routine cases eighteen weeks. To offset this the two routine cases were probably more serious in type. While all four cases were "mixed" infection, one routine case presented actinomyces as well.

IMPROVEMENT IN CASES UNDER VACCINE THERAPY
AS CONTRASTED WITH THOSE UNDER
ROUTINE TREATMENT

Possibly the most noteworthy result observed was the rapid drying up of cervical discharge in the acute and subacute cases primarily due to the gonococcus. This was noted in fourteen cases (two acute, ten subacute and two chronic). This was noted to a lesser degree also in the urethral discharges.

The erosions of the acute and subacute stages, which were due primarily to the gonococcus, responded well. In the chronic stage with erosions due to "mixed" infection the vaccine did not give good results.

The improvement and rapid disappearance of old chronic pyosalpinges reported by some was not generally verified in this series, though in one case there was a dramatic disappearance of a pyosalpinx. But even in this case the outcome was not different from that often noted in the subsidence of pyosalpinges under routine treatment.

Table 3 shows the percentage loss of mobility of the uterus at the beginning and the end of treatment.

GROUP ON SMALL DOSES

The group of five cases on small doses of vaccine (up to 3 billions) has responded extremely well to vaccine therapy. However, there were one subacute and four chronic cases.

In the subacute case there was a severe clinical course but the patient made an excellent recovery. None of these patients had erosions or a very profuse discharge and hence the treatment was not put to a severe test.

One patient had a Bartholin abscess, which in spite of the vaccine had to be incised.

The perimetritic improvement in this series was good.

INFECTION OF URETHRA AND SKENE'S GLANDS

There was nothing especially striking in the results of vaccine therapy in infections of the urethra and Skene's glands.

In chronic cases in which there was a persistent urethritis or skenitis, the vaccine had little or no effect, undoubtedly because the continued infection was due

TABLE 3.—Comparison of the Improvement of Perimetritis as Evidenced by the Percentage Loss of Mobility of the Uterus

	Vaccine Treatment		Routine

to an organism other than the gonococcus. The more persistent chronic foci had to be treated by other routine procedures.

It is questionable whether the extremely high dosage is justifiable; for instance, one patient who had a dosage up to 48 billion and had a marked reaction seemed to have no signs of improvement. On the other hand, in the case of the pyosalpinx that dramatically disappeared a dosage up to 50 billion had been administered.

The behavior of the complement fixation test is a matter that must receive consideration, for these patients subjected to vaccine therapy show a high complement. Dr. McNeil studied especially interesting cases and followed the readings up to 40 plus and 50 plus. Probably these high complement readings persist longer than in

the cases not treated by vaccine and it therefore becomes necessary to discharge these cases with a fairly high complement reading. Dr. McNeil states that the complement subsides satisfactorily in these cases and in the cured cases returns to normal in from sixty to eighty days. More work is needed in this follow-up serologic survey.

CONCLUSIONS

1. Vaccine therapy is not a specific for the cure of gonorrhea. It is, however, probably a very valuable form of treatment in the acute and subacute stages of the disease. This is probably true also in chronic cases in which the main offending organism is the gonococcus. It is probably not of value in cases due to "mixed" infection.

2. In the acute and subacute stages, vaccine therapy will probably shorten the period of hospitalization. However, the great drawback of severe reaction from this treatment, especially with large doses, is to be considered.

3. It is questionable whether very large doses are justifiable, because of these reactions.

4. Probably vaccine therapy in smaller doses combined with indicated routine treatment would be a more desirable type of treatment.

5. Vaccine therapy is of sufficient importance to warrant further careful study into dosage, complement fixation reaction, and tests for proof of cure.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. PELOUZE, HERROLD AND BARRINGER

DR. HENRY W. E. WALTHER, New Orleans: Advances in the therapy of gonorrhea have not been made proportionate to the progress noted in handling surgical lesions of urogenital origin. A frank interchange of opinion by those with extensive clinical experience will clear up many hazy conceptions now current. The newer vaccines, the filtrates and the bacteriophages open an interesting field in the treatment of gonorrheal infection and one worthy of serious consideration. I cannot feel that the indifference and the lack of cooperation on the part of many individuals fully explain the failures in handling the most intelligent patients; yet they go through a siege of complications sufficient to discourage the best of clinicians. I feel downhearted when a married man comes into my office, for I know, before starting treatment, that he is going to have a long, hard time of it. Among patients from the very best families, complication after complication comes along; yet let the newsboy or the iceman be treated and the condition promptly clears up in two or three weeks. The treatment is the same all the way through but the results are not uniform. The matter of actinomycosis brought out by Dr. Barringer is of great interest. In my clinic I have found that practically 100 per cent of all females coming in for gonorrhea have gonorrhea. The time has not yet arrived when the high frequency current can be dispensed with in the treatment of localized and accessible gonorrheal pockets of infections. The skenoscope will expose Skene's glands so they can be destroyed with the high frequency needle. The Hyams technic of a cautery loop for coning the cervix in gonorrheal cervicitis is a method superior to any other so far advocated.

DR. HERBERT T. HAYS, Houston, Texas: Dr. Pelouze, Dr. Herrold and Dr. Barringer make no mention of the treatment of rectal gonorrhea. Any one treating a great deal of urogenital gonorrhea is certain to see rectal gonorrhea occasionally in the male and frequently in the female. In my own series I would estimate the occurrence of rectal infection following urogenital gonorrhea in the female to be from 35 to 50 per cent. Patients with a normal rectum contracting the infection frequently immunize themselves and get well without any treatment. I think this is why it is often overlooked. If there is much rectal disorder, such as fistulas, hemorrhoids, infected crypts, fissures, prolapse and stricture, they usually

have a hard time. The infection will drag out over a long period. Dr. Pelouze mentions that good drainage makes for good curative response. This is true of gonorrhea of the rectum, and I think it is because of the pocketing and retention of pus in the various pathologic structures that are present, which creates the chronicity of the disease in this region. The local treatment of this condition is the same general routine as followed in urogenital gonorrhea; that is, the usual instructions in the care of the general health and instillations into the rectum of some of the very mildest antiseptics. I use mild silver protein (5 per cent Argyrol, 3 per cent Solargentum) or some of the other very mild silver salts. I inject these solutions into the rectum with a blunt-tipped syringe by placing the tip of the syringe against the anus and forcing the fluid in by pressure on the bulb. Insertion of instruments into the acutely inflamed rectum is liable to cause trouble the same as it would if a catheter or sound should be put into an acutely inflamed urethra. In the very persistent type of infections in which hemorrhoids, fistula and cryptitis are the factors causing the chronicity, it is best to operate on these complications and eradicate them when possible, and the patient will then usually get well. Stricture of the rectum, however, is an exception. With urethral strictures the infection usually clears up, but not so in strictures of the rectum. These often drag on for years.

DR. ROY W. MOHLER, Philadelphia: Acute gonorrhea in the female is a self-limited disease and needs no special treatment. The discomfort of the infection may be allayed by a simple sedative. The vagina may be cleansed by simple low pressure douches. All antiseptics except in very low dilution should be avoided, because they lower the inherent resistance of the epithelium against the infection. Topical applications to the cervix and physical influences, such as coitus, swimming, bathing or diving, which increase intravaginal pressure, should be avoided, since these factors definitely influence the extension of the infection. I have not been able to note any association between pelvic inflammatory disease and menstruation, except as it has been associated with the foregoing physical influences. The acute stage of generalized infection subsides in from two to six weeks and localizes in Skene's tubules, the urethral glands, the cervix and, less frequently, in Bartholin's glands. Dr. Pelouze has pointed out in his studies the importance of good drainage in the eradication of gonorrhea, and these are the local points where free drainage is often not possible. To eradicate these poorly draining focal areas of infection, the urethra is anesthetized by the application of 10 per cent cocaine solution. The urethral glands and Skene's tubules are isolated by probe and are electrocoagulated. This may be repeated at intervals of three weeks until all the tubules have been destroyed and resolution is completed. The persistent infection of the cervix is eradicated by destruction of the infected mucosa in the lower two thirds of the cervical canal. This may be accomplished by a number of methods; the method most easily adapted as an office procedure is electrocoagulation. The cervical mucosa must be sufficiently treated so that the racemose glands and the columnar epithelium of the canal will be replaced by squamous epithelium. If the coagulation is too extensive, the cervical musculature will be destroyed and stenosis of the type that has interested Curtis will occur. After resolution of the urethra and cervix is complete, the secretion from these areas is examined for pus cells. If pus cells are absent, one can be sure that gonococci are absent and that cure is complete.

DR. AUGUSTUS HARRIS, Brooklyn: Dr. Pelouze has stressed the importance of the local tissue defense mechanism and the prime significance of maintaining this immunity response at all times by gentle treatment. The fullest cooperation of the patient in the care of himself is imperative. Until more is known of a specific biochemical nature, rapid cures cannot be expected. Much, however, can be accomplished by meticulously careful and gentle handling of the patient. Strenuous or intensive efforts to effect a rapid cure are likely to result in a protracted and complicated course. I have obtained the best results with the use of silver potassium cyanide-potassium oleate (under the trade name of Silvogon) and also with dilute solutions of acriflavine base. One cannot emphasize too strongly the individualizing of every patient and changing and altering

treatment in a given case as indicated. Another phase of the problem involves a serious responsibility on the part of urologists. I refer to the urgent need of the proper clinical training of those practitioners who treat gonorrhea without adequate experience. Until something tangible is done to provide training for inexperienced practitioners who treat these cases, or until physicians generally are coerced into referring them to the urologist or to urologic clinics, a wide and uncovered group of uncured patients will prevail. I congratulate Dr. Herrold on his results in mentioning forty-eight out of a hundred cured patients with anterior urethritis without a posterior involvement. I should like to ask him how he proved the absence of posterior involvement in these cases. The average time for cure he states in this group was twenty-seven days. He also reports six to nine weeks cures in most of the posterior urethritis cases. These results are definitely superior to any that I have been able to obtain in a given series. Dr. Herrold states that he has found negative shreds for gonococci over a period of fifteen to twenty-five days after beginning treatment in half of the anterior urethritis cases. I should like to ask Dr. Herrold how much confidence he places in the silver provocative test; also what constitutes a clean bill of health for the patient? Antigens, foreign proteins and mixed vaccines have been of definite service to me as an aid in the treatment of the complications of epididymitis, prostatitis and rheumatism. In the not distant future a paper will appear on the subject of uroscopy, and a reprint will be sent to all members of the American Urological Association. I hope with the cooperation of urologists that the ideal may ultimately be approximated of having all practitioners adopt uroscopy, or the gross examination of the urine, as a routine measure and learn to follow the progress under treatment not only of cases of gonorrhea but also of any infections of the urogenital tract.

DR. A. L. WOLBARST, New York: Several points in Dr. Herrold's paper impressed me. His conclusion that the application of an antiseptic once daily is sufficient and often safer than more frequent applications impressed me particularly. I have been advocating this principle for thirty years, but this is the first time I have seen it corroborated by others. Not only is it better and safer to give one injection a day, but the solution used must be as mild as possible, not as strong as the patient can bear. I use mild silver protein in 3 per cent strength, gradually increased to 5 per cent, and only once a day, rarely twice. I have had the most satisfactory results in thousands of cases treated that way, with almost no complications of any kind. Everything put into the urethra is a foreign body; the inflamed urethra is red, hot and tender, and yet physicians have been putting chemicals in it that only add to the irritation; and in that I include acriflavine. I don't understand why the risk of producing a silent stricture is taken when silver preparations are available that are equally effective, probably more so, without the element of danger.

Dr. Herrold has brought out an interesting point in connection with his use of acriflavine. He said he used "an English preparation," presumably made by Boots, which is said to be less damaging than the American preparations. Also in his paper he said he alternated his acriflavine with "a mild silver preparation." Which one did he use? There are some twenty-five or thirty, all different and with different therapeutic values. Why not mention the name? I am standing under the roof of the American Medical Association and it is considered rank heresy to come here and talk about these proprietary silver preparations which we all use, but hesitate to mention by name. We should know just what we are talking about. If you write an article and in it you say you used Argyrol or Silvol or some similar product, some one in the editorial office will substitute for the specific name a generic term which does not mean anything to the reader. It is fair neither to the reader nor to the author. We are afraid to talk frankly about these things because of their ethical aspects, yet we talk freely of mercurochrome and acriflavine. Why the distinction? We should get together some day and agree to the common sense view that it is perfectly proper and ethical to mention by name any product that we use or don't use. Then we may get somewhere in our treatment of gonorrhea. Dr. Walther has referred to members of the best families having gonorrhea and developing complications because of the domestic affairs of

the individual. I beg to differ with my friend. I think those cases go bad because the doctor becomes nervous and worried over the fact that he is treating a member of a best family; he tries to do too much, he tries to cure the case too quickly and there is where the damage occurs. He gets nervous and loses control of the case. It's like a man getting an attack of nerves while driving an automobile or an airplane. Complications result. It must be remembered that the less local treatment is given these patients and the milder the products used, the better they will respond and the fewer complications will result. But one must not go out for a time record in curing gonorrhea. This eagerness to cut down the time is dangerous. It isn't done in typhoid, in pneumonia or in other infections. The same must be done in gonorrhea. Nature must not be obstructed through overzealous treatment. That is the key to the cure of gonorrhea and the prevention of complications.

DR. A. G. FLEISCHMAN, Des Moines, Iowa: I was rather surprised that Dr. Barringer omitted the important part played by the various physical agents now available. I refer particularly to surgical diathermy. Years ago I became interested in this physical agent because of the many failures I had in the treatment of gonorrhea in the female with other methods. I carried out quite an extensive clinical investigation. A few years ago I recorded a hundred cases of specific gonorrheal endocervicitis that were treated by surgical diathermy. Out of these hundred cases I had the privilege of watching quite carefully 70 per cent, and in these cases I was able to obtain clinical and bacteriologic cures. I want to call attention to a method of electrocoagulation that is not original with me. I refer to the biterminal method of producing electrocoagulation by the procedure that was devised by Dr. Endy of New York. Dr. Endy found that in most cases in which he carried out electrocoagulation of the cervix, in which a large dispersing electrode is used on the abdomen and a small active electrode in the cervix, he had difficulty in determining the proper depth of the coagulation and also that, frequently at the time of the separation of the slough, many bad secondary hemorrhages occurred. Dr. Endy conceived of an electrode that utilized what is known as two electrodes embodied in one instrument, the two of the same dimension, and by this method he determined that he could know with a certain setting of the current and with a certain duration of applications that he could predetermine the depth of coagulation before the actual procedure was carried out. By this method it is possible to coagulate to a depth of from 2 to 4 mm. and to eliminate the tendency toward secondary hemorrhages. I want to reiterate that electrocoagulation, particularly in the subacute and chronic cases of specific endocervicitis, is an excellent method of treatment.

DR. P. S. PELOUZE, Philadelphia: I endorse what Dr. Harris said about the need of better training for those who treat gonorrhea. In a recent survey of 283 consecutive office cases of gonorrhea, this need was brought out strongly. Of 100 patients presenting themselves for treatment before the fifth day of the disease, fourteen had a posterior urethral infection when first seen. A number of these followed intravesical irrigation by other physicians. The average duration of cases in which posterior infection did not take place was 5.6 weeks. During the same period, 183 patients presented themselves after the fifth day of the disease. All but twelve had a posterior infection when first seen and only two eventually escaped it. In their histories, seventy-eight of these patients had eighty-nine complications other than posterior involvement. Almost all of these patients had been under a physician's care and many of the complications were due to the type of treatment given. The average time required for cure was sixteen weeks. It is thus obvious that, if posterior involvement is to be prevented, gentle local treatment must be started before the sixth day of the disease. It is equally apparent that there is great need that the public be apprised of this fact.

DR. RUSSELL D. HERROLD, Chicago: In regard to the remark of Dr. Hayes, rectal gonorrhea does not apply particularly to my paper but I agree with him that it is undoubtedly common in females. In answering Dr. Harris, I would define my period of cure as rather the period of infectivity of the gonococcus in distinction to postgonorrheal conditions. It is more of a statistical report of the actual time after which I was not

able to find the gonococcus. In posterior infections, the six to nine weeks cure was determined from the period that they became posterior, or from the period that the patients came to me, which in the latter instance was from four to six weeks after the onset. The cure would therefore be between three and four months from the time of the initial infection. In regard to the seemingly good results in the anterior infections, I should like to stress here what I was not able to stress in the paper, that six to one of the group of patients who had previously had gonorrhea were cured in the anterior stage, while only slightly more than half of the patients with first infections were cured without posterior complications. I have found that the shred examinations are quite reliable as a means of determining when the gonococcus has disappeared, but those patients are kept under observation and treated for their post-gonorrheal conditions for a much longer period. With regard to Dr. Wolbarst's questions, I stated that acriflavine was not considered to be the only drug that would produce good results. Acriflavine was not mentioned by trade name because this study was based on clinical experience. I have had similar experience with other preparations of acriflavine when the toxicity was decreased by incorporation in gelatin, but the aqueous solution is more practical for general use and, until such time as laboratory tests prove exactly the difference in toxicity, I do not feel like condemning one product or eulogizing another. I want to say one thing about vaccine therapy. I should like to stress that cases should be divided into mild and severe infections, and that mild infections be considered as applicable for local treatment, and that in my experience mild infections proved to be cured in a shorter period than any vaccine series that I know of. Therefore I believe that local treatment should be considered first for mild infections. The group of severe infections can be subdivided into two groups: one that will respond favorably to vaccines and one that will respond unfavorably. The latter group may be investigated for improved biologic therapy, after which its use would seem more justified in the mild anterior infections. The host is one thing; an antigen is another. There is more variation in the host than there is in any antigens that have been described. Therefore the future work should deal with other factors more than the antigen itself, particularly the size of the dosage, the interval between injections, and the route of injection.

DR. EMILY DUNNING BARRINGER, New York: The cases of rectal infection that I recorded were observed in a large venereal service at Kingston Avenue Hospital, where there are upward of 100 beds devoted to gonorrhea or syphilis. I was much impressed with the fact that rectal gonorrhea as such was rather rare in the service. I cannot give a reason. At one time an investigation was made, cultures being taken in suggestive cases, but it was felt that unless there was a definite indication calling for that special examination it would not be done as a routine, and it has not been done as a routine since the time the survey was made. In regard to the routine treatment, evidently I did not make myself clear. I left that whole section out in reading. In the paper, the details of the routine treatment are given, covering the treatment for the acute stage, the subacute and the chronic. In the acute stage, first of all, as nearly absolute rest in bed as can be given is stressed, with lack of trauma and a minimum of treatment. In the very acute cases of vulvitis only irrigation over the vulva is advised and later if the invasion is passing up toward the cervix very low pressure douches of mild, nonirritating antiseptic washes are given. An effort is made to give as little treatment as possible in the acute stage, in the hope that it will not become an infection of the upper tract. In the subacute, with the various complications, a variety of treatment is given according to the indication. Each case is individualized as much as possible. However, in the unexceptional case a certain standard routine treatment is employed. In the chronic group, all the surgical complications have to be considered. There are so many very important surgical indications in the subacute and chronic stages that time would not permit my going into them. I wish to make it clear that I sacrificed routine treatment in order to discuss the vaccine therapy. The results have been excellent with electric cauterization and coagulation, and with the Elliott treatment in selected cases. I wish to state again that the supreme thing is first of all the diagnosis and then the individualization of treatment.

THE FREI TEST FOR LYMPHOGRANULOMA INGUINALE

RECOVERY OF THE ANTIGEN FROM A PUSTULAR REACTION

MAURICE J. STRAUSS, M.D.

AND

MARION E. HOWARD, M.D.

NEW HAVEN, CONN.

In discussing a paper on lymphogranuloma inguinale presented by DeWolf and Van Cleve¹ before the Section on Dermatology and Syphilology at the meeting of the American Medical Association in 1932, Weidman called attention to the fact that practically nothing was known of the nature of the antigen. In addition to this, nothing is known of the exact nature of the reaction itself. Because of its similarity to the tuberculin test and the trichophyton test the assumption is made that it is due to a reaction between the specific antigen obtained from infected tissues or pus from the abscesses, and antibodies.

We report the results of a short series of experiments that may shed some light on the nature of the Frei reaction. These experiments are few because of the small amount of material and therefore it is hoped that they will be confirmed by future work. The cases used in these experiments included case 1 (E. R.), a clinically typical case, strongly positive to a known Frei antigen, which furnished some of the experimental antigen used; case 2 (H. B.), an atypical case in which a large abscess and little periadenitis were present; case 3 (L. M.), a typical case presenting, in addition, a large abscess; case 4 (V. N.), a rectal case in which there were fistulas exuding pus; case 5 (A. B.), a rectal case in which there were no fistulas but a typical stricture; case 6 (J. L.), a clinically typical case, and case 7 (A. A.), a severe case in which there was one particularly large abscess from which further experimental antigen was obtained.

EXPERIMENTAL PROCEDURE

In case 1 the Frei test produced a central pustule from which approximately one-twentieth cubic centimeter of thick pus was aspirated under aseptic conditions. This was diluted ten times with physiologic solution of sodium chloride and inactivated at 60 C. for two hours on one day and one hour the next day. This material was used in exactly the same manner as Frei antigen in five of the cases and one control. In addition to this material, intradermal injections were made at the same time with the following antigens: a known positive antigen received through the courtesy of Dr. M. B. Sulzberger; a Frei antigen made from pus from the glands in case 1 (used only in cases 1 and 2); an antigen made from the filtrate of pus from case 2; an antigen made from gland tissue in case 1 and the filtrate of the latter. The results are shown in table 1, in which + + + denotes large red areola with a central papule capped by a vesicle; + + smaller red areola with a central papule, + definite papule with very slight red areola; ± red papule but no areola, 0 negative, and — not done.

From the Department of Dermatology, Yale University School of Medicine and the New Haven Hospital.

Read before the Section on Dermatology and Syphilology at the Eighty-Fifth Annual Session of the American Medical Association, Cleveland, June 15, 1934.

1. DeWolf, H. F., and Van Cleve, J. V.: Lymphogranuloma Inguinale. J. A. M. A. 99:1065 (Sept. 24) 1932.

The complete failure to obtain positive reactions with antigens 4, 5 and 6 is evidently due to some technical error in preparation of the antigen because, although some workers have been unsuccessful in using filtrates as antigens, the antigens made from excised glands have been uniformly positive.

There was only enough of antigen 2 to test two cases, but in both it gave a less marked reaction than antigen 1, a result quite in accord with the general view that different antigens vary in potency.

Regarded as a group, the reactions to antigen 3, the experimental antigen, were much weaker than to anti-

gen 1, the known positive antigen. The explanation of this is quite obvious when one recalls that the pus had to be diluted.

The results of these experiments raise two questions. First, would any purulent material from a patient with lymphogranuloma inguinale cause this reaction? In other words, is this reaction caused by a substance in the body of such patients which would appear in any reaction severe enough to cause a vesicle or a pustule? Second, would any purulent material cause this reaction in any patient with lymphogranuloma inguinale; that is, is the reaction a nonspecific one? It was felt that these two questions could be answered at the same time if nonspecific material could be obtained from a patient with lymphogranuloma inguinale. Accordingly, when at a later date case 7 showed a pustular reaction, the pus was aspirated and treated the same way as in the previous experiment except that it was diluted only five times. One one-hundredth milligram of old tuberculin

9. J. L.	+	+	0	0	+
Control	0	0	0	0	0

was injected intradermally into the same patient. This gave a papular reaction but no vesicle. One-tenth milligram and one milligram were then injected. The latter caused the formation of a pea-sized vesicle, with purulent contents. This was aspirated and treated in the same manner as the material from the Frei test. Intradermal tests were made on the same patient and two other patients with lymphogranuloma inguinale, one of whom had been used in the previous experiment, and on one control. The results are given in table 2.

These results confirm those of the first experiment and it is worthy of note that in case 6 there was already a diminution of the sensitivity to the test, as the reaction to the known antigen was less marked than it had been previously. In addition, it should be noted that the material from a tuberculin test in one of these patients gave no reaction in any of the patients tested.

COMMENT

These few experiments suggest that the contents of the pustule resulting from the Frei test contained an antigen identical with that of Frei. If this is true, three possibilities suggest themselves: (1) The active principle of the antigen is present in the blood and is found in the pus as a result of this. (2) new antigen was formed just as it is in active lesions, or (3) some of the antigen injected into the skin was still present and was recovered in the pus.

The first possibility does not seem very probable, as the injection of Frei antigen would simply be adding a substance already present. Also, if this were true the antigen should be present in the material from the tuberculin test and the second experiment shows this to be absent. To accept the second theory would be to assume that the Frei test is an inoculation with the disease in this case. That this was not true is quite evident. The patient developed no satellite adenitis nor did any other patients with lymphogranuloma inguinale or controls in whom this antigen was used. There remains, therefore, the third possibility, which seems quite tenable. We assume that a reaction to an intradermal injection is due to the coming together of two substances, antigen and antibody. The fact that

Fig. 1.—Pustular reaction to Frei antigen. It was from this that the experimental antigen in experiment 1 was obtained.

this particular reaction was markedly different from the usual reaction suggests the possibility of a quantitative difference; that is, either too much antigen or too many antibodies. The fact that an increase in the amount of antigen gives a more marked reaction is a well known fact as in the graduated tuberculin test the less diluted the tuberculin the stronger the reaction. In this case we had a particularly potent antigen, as it gave a stronger reaction in this patient than the homogeneous antigen, so it seems fair to assume that the excess of concentration occurs on the antigen side. This suggests that the antibodies responsible for the Frei reaction are fixed antibodies rather than circulating antibodies; for if they were circulating antibodies no excess of concentration of antigen could occur, as there would be an indefinitely large supply of antibodies available, while if one is dealing with fixed antibodies the supply of these would be limited to that already present in the circumscribed portion of epidermis affected by the antigen.

In 1922 Thomas and Arnold² noted a blister-like reaction to a Piquet test. They raised the question what the contents of such a blister would do if injected into children with tuberculosis. In order to cause a

² Thomas, E., and Arnold, V. *Experimentelle Blasenreaktion. Mischchen und Welschsch. 62:11, (Feb. part 1) 1922.*

blister they employed a 1:1,000 solution of cantharides in collodion. This was painted on the site of a positive Pirquet reaction thirty-six hours after the onset. After twenty-four hours a definite vesicle appeared and the contents were aspirated and diluted with five parts of physiologic solution of sodium chloride. Intradermal tests were made with the following substances: (1) tuberculin 1:100,000; (2) tuberculin 1:100,000 with vesicle contents diluted as before mentioned; (3) a mixture of the diluted vesicle contents and saline solution alone. In twenty-nine cases out of forty-three tested the reaction to the mixture of tuberculin and vesicle contents was stronger than that to tuberculin alone or to vesicle contents alone. In nine the reactions were alike and in five the reaction to tuberculin plus vesicle contents was weaker. As a control they used the contents of blisters raised over nonspecific inflammations. These were completely negative in seventeen cases. In discussing this reaction they raise the question as to whether remnants of tuberculin were present but rule this out by stating that after thirty-six hours no tuberculin could be left and also because of the fact that the increase in the reaction was too great to be explained by an insignificant amount recovered. However, when they state that the reaction to the mixture of tuberculin and vesicle contents was stronger than to vesicle contents alone they imply that there was a definite reaction to vesicle contents alone. If the substance recovered was only, as Thomas and Arnold deduce, an activator of tuberculin, one would expect the reaction to vesicle contents alone to be negative. It is difficult to conceive of a substance giving a reaction regularly in tuberculous children unless it is tuberculin. Thomas and Arnold offer no explanation at all for this reaction.

In 1923 Karl Gottlieb³ carried out a similar experiment using only the contents of spontaneous vesicles after Pirquet tests. This substance gave positive tests in tuberculous individuals. He excluded nonspecific

Fig. 2—Experiment 1, case 3, showing at *A* positive Frei test and at *B* similar but less marked reaction to the experimental antigen.

reactions because nonspecific substances gave much weaker reactions in the same subjects. He allowed the vesicles to refill and aspirated the contents again. This substance gave a weaker reaction than the one used before. This procedure was repeated the next day and the reaction was still weaker. Gottlieb also considered the possibility of the presence in the vesicles of rests of tuberculin but discarded this in favor of the theory that the reaction was due to some specific substance in the serum. It seems to us that this theory could offer no explanation of the progressive weakening of the

reaction. On the other hand, rests of tuberculin could be expected to be in less concentration each day.

These two experiments seem to parallel ours and although the writers do not come to the same conclusion that we do it does not seem to us that their experiments exclude our theory. On the contrary, several of their results seem to strengthen it.

It will be noted that in our first experiment the reaction to the experimental antigen was negative in the subject from whom it was obtained. We can offer no explanation of this phenomenon but wish to note

Fig. 3—Experiment 2, case 3, showing at *A* positive reactions to Frei antigen, and at *B* similar but less marked reaction to the experimental antigen; at *C* experimental antigen diluted 1:20 was injected, at *D* antigen from the tuberculin test. There was no papule here, the dark area being due to ecchymosis.

that Thomas and Arnold found that the occurrence of weaker reactions (as compared to reactions from tuberculin only) occurred in the patient from whom the material was taken.

CONCLUSIONS

Realizing that the series of experiments is small, we do not feel justified in drawing definite conclusions but would say rather that our results suggested that:

1. If a Frei reaction is strong enough to cause vesicle formation, the contents of this vesicle are capable of producing a reaction similar to the Frei reaction in patients with lymphogranuloma inguinale.

2. The substance causing this reaction is probably a reminder of the Frei antigen originally injected and not combined with antibodies.

3. These antibodies are not circulating antibodies but fixed antibodies.

It is realized that this brief experiment is not conclusive but we feel that it is expedient to publish the results so that they may be repeated by others who have more material at their disposal and that further experiments which ours suggest may be undertaken.

41 Trumbull Street.

ABSTRACT OF DISCUSSION

DR. MAX S. WIEN, Chicago: Drs. Strauss and Howard have demonstrated that purulent material occurring in the course of a positive Frei reaction is capable, when diluted and prepared as Frei antigen, of giving weakly positive reactions in lymphogranuloma inguinale. They raise the question as to whether this reaction is a result of the formation of new antigenic substances as a result of the Frei reaction or whether it is due to a remainder of Frei antigen that was originally injected at this site and did not combine with the antibodies at the injected site. I have repeated their experiments with material obtained from two patients. The first case was a white man with lymphogranuloma inguinale of the classic inguinal variety of three weeks' duration. A strong antigen gave a pustular Frei reac-

3. Gottlieb, Karl. Untersuchungen mit dem inhaltblasiger Tuberkulinhautreaktionen, *Ztschr. f. d. ges. Exper. Med.* 36:1, 1923.

tion, and 0.05 cc of this pus was then removed, diluted ten times, treated in the usual manner, and injected in four known cases of lymphogranuloma inguinale, and in one control. All the reactions were negative. The second patient was a Negress with the genito-anorectal syndrome, in whom a pustular Frei reaction was obtained, and in addition she developed a focal flare-up of the esthioniene. I obtained 0.05 cc of pus from this Frei pustule, prepared it in the usual manner, and tested four controls. All the reactions were negative. Also histologic studies were made of Frei papules in these patients. It revealed a nonspecific infiltrate such as is seen following the intradermal injection of any type of foreign protein. There was nothing in the section that in any way simulated the picture of lymphogranuloma inguinale. Also Frei antigen was prepared from the straw-colored serous exudate that sometimes occurs in the glands a few days after primary puncture of the fluctuant gland to secure Frei antigen. The clear, straw-colored fluid obtained which I felt was akin to blood serum, was treated in the usual manner for preparing Frei antigen, injected in a series of known cases of lymphogranuloma inguinale and controls, and gave negative Frei reactions. These results suggest an absence of any circulating antibodies as indicated by the work of Calata and (Actas de mayo 25:443 [April] 1933). On the basis of these observations I feel that the Frei test is specific and that this specificity is most probably dependent on certain fixed substances that reside in the skin of these allergic individuals. I agree with the conclusions suggested by Drs. Strauss and Howard that any positive reactions obtained with purulent material resulting from a positive Frei test is most probably due to the fact that some of the originally injected antigen was still uncombined in their tests and was capable of giving a reaction when subsequently tested.

DR WALTER S. GRANT, Chicago. I have had the privilege of observing forty cases at the Provident Hospital in Chicago. Ten of these were of the anorectal syndrome type. It has been my experience to observe pustular reactions in some cases of long standing and due either to hypersensitiveness or to a very potent antigen, but I have never made any attempt to recover the antigen from these pustules. I wish to ask the authors what their experience has been in obtaining positive Frei tests in children or in cases of lymphogranulomatosis in children.

DR JOHN ERIC DALTON, Indianapolis. I have had an opportunity to study two children born of mothers who suffered from acute lymphogranulomatosis inguinale. The acute glandular process in one of the mothers occurred just preceding the conception, while in the other it appeared during the pregnancy. In each case the child has been watched with periodic Frei tests, over a period of a year, with completely negative results. A report dealing with lymphogranulomatosis inguinale in children appeared in the *Klinische Wochenschrift*, Aug. 13, 1932. Infection in two girls, aged 6 and 7, who slept in the bed with a known infected female cousin, are reported there. These were believed to be accidental contaminations.

DR ELMORF B. TAUBER, Cincinnati. By using a special medium I think I have succeeded in cultivating this virus. The work came out with vaccinia virus first in the *British Journal of Experimental Pathology* by Matland and Leith, who used Tyrode's solution with rabbit tissue. I used the Tyrode solution in the dilution of 1:5 with guinea-pig tissue. The suspected pus which was checked by a control by Frei antigen uncontaminated was placed in this solution diluted with 1:10 saline solution. Dr. Joseph Tamuro in the bacteriology department who conducted most of the experiments, found that on the third to the fourth day a slight cloudiness appeared in the tubes. This persisted until the twelfth day, but after that it always became clear or tissue destruction (disintegration) took place. He was able to carry this for as much as twenty-five or thirty transfers. We have also begun an experiment in a series of cases to use this as a therapeutic measure. The results so far seem to be about the same as those obtained with Frei antigen treatment, irradiation and excision. I believe that possibly the disease is self-limited, since the cases that were left alone seemingly did quite as well as those treated.

DR MAURICE J. STRAUSS, New Haven, Conn. It would have been very gratifying if Dr. Wien could have confirmed our results entirely. I agree with him that his histologic exami-

nations rule out the possibility of this being an inoculation with the disease and hence the formation of new antigen. Also that his work with the serum appearing in the glands and the work on blood serum which he quoted rules out the possibility that the antigen appears in the serum. In answer to Dr. Grant's question I have never seen lymphogranuloma inguinale in young children. However, I can say that when we began our work with lymphogranuloma inguinale we tested children with a known antigen as controls, and they were all negative. Dr. Tauber's cultivation of the virus is extremely interesting and most important. It seems that this might be the answer to the question that Dr. Weidman raised yesterday about whether antigen can be made commercially. If virus can be found, antigen can probably be produced quite readily.

INTRACAPSULAR FRACTURE OF THE HIP

REPORT OF ONE HUNDRED CONSECUTIVE CASES

LOUIS G. HOWARD, M.D.

AND

KENNETH CHRISTOPHE, M.D.

BOSTON

One hundred consecutive intracapsular fractures of the neck of the femur treated at the Massachusetts Memorial Hospitals by nonsurgical methods have been reviewed. The purpose of the study was an endeavor to compare the end results of treatment by the abduction double plaster spica of Whitman¹ with the end results obtained by traction and internal rotation of Peckham² or Ruth³. Also it was planned to determine, if possible, the type of femoral neck fractures that consistently gave poor results under either kind of treatment. The study soon showed that accurate comparisons of the two methods would be impossible, because in general the more difficult cases were treated in plaster. However, the investigation showed several types of fractures in which each method gave many deaths or nonunions. Therefore the survey appears to be of some value in

TABLE 1—Treatment and Results

Treatment	Died	Survived	Totals
Untreated	1	0	1
Whitman	19	56	75
Traction and internal rotation	3	25	28

*11 per cent of the Whitman patients died
10.7 per cent of the traction patients died

determining roughly a group of cases in which surgery should be considered.

The series of 100 patients included eight males and ninety-two females, with an average age of 67 years. The age extremes were 12 and 89 years. The average period of immobilization was from ten to twelve weeks and that of hospitalization about fourteen and one-half weeks for either method of treatment. There are no extracapsular cases in this series.

Nineteen hospital deaths occurred. These were due largely to bronchopneumonia (six), pulmonary embolus (five) and cardiac disease (three). Other causes of

death were diabetes (two), carcinoma (one), cerebral hemorrhage (one) and cerebral thrombosis (one). Seventy-one were treated by the Whitman method with fifteen deaths, and twenty-eight by traction with three deaths. One untreated case resulted fatally.

Of the 100 patients, nineteen died and twenty-one are reported as "unknown." The "unknown" are

patients who were not followed up one year or more after treatment. Sixty cases were carefully examined and followed one year or more after discharge. Of these, forty-nine were examined by members of the orthopedic department. Eight others were reported in detail by other physicians and institutions and three more were reported by patients or relatives of patients

Fig. 1.—Good result showing bony union and normal relation of fragments. Most fractures at a right angle to the femoral neck will unite without much absorption if properly reduced.

with sufficient accuracy and detail to permit them to be included in this series. Seventy-one patients were treated by the Whitman method and twenty-eight by the traction and internal rotation method. The end result study, as regards bone union or nonunion and the sources of information, is shown in tables 2 and 3.

RELATION OF LOCATION AND TYPE OF FRACTURE TO END RESULT

The location and type of fracture determined the end result to a large extent, regardless of the selection of treatment.

Subcapital fractures of the neck gave good results. Out of fifteen of these there were fourteen with bone union and one death. In three cases of comminuted subcapital fracture there was one death, one bone union and one nonunion.

The central fracture gave poor results. In thirty-one of these there were four deaths, nineteen bone union and eight nonunion. In eighteen comminuted central fractures there were five deaths, eight bone union and five nonunion.

The roentgenograms were destroyed in twelve cases and these were recorded simply as intracapsular. Study

Fig. 2.—Because of arthritis and long immobilization during treatment, the head united to the acetabulum. The neck refractured when adduction was permitted after removal of the Whitman abduction plaster.

of this group showed eight deaths, two bone union and two nonunion. Undoubtedly most were "central" or "central and comminuted."

Table 4 illustrates the relation of location and type of fracture and treatment to the end result. Study of the table is somewhat deceiving as regards end result and treatment, because the more simple cases were treated by traction. However, the table definitely shows that the greatest number of nonunions and deaths occurred in fractures of the central portion of the femoral neck, and that nonunion and mortality increased rapidly when the fracture was comminuted.

TABLE 4.—Relation of Location and Type of Fracture to End-Result by Treatment as Regards Bone Union, Nonunion and Death

Location and Type of Fracture	Whitman			Traction		
	Bone Union	Non-union	Died	Bone Union	Non-union	Died
Subcapital 15	10	0	0	4	0	1
Subcapital and comminuted 3	1	1	0	0	0	1
Central 31 (1 died untreated)	12	8	3	7	0	0
Central and comminuted 18..	6	2	5	2	3	0
Recorded simply as Intracapsular 12	2	1	7	0	1	1
Totals 79.....	31	12	15	13	4	3

This table includes the nineteen hospital deaths and the sixty cases followed through for final end result report.

Careful roentgen study showed several other facts. A transverse simple fracture in a plane at right angles to the column of the neck generally united whether the location was subcapital or in the central portion of the neck. The percentage of nonunions and the degree of shortening of the femoral neck rapidly increased with the obliquity of the fracture and the degree of comminution. Slight separation of a small fragment frequently tended toward absorption and nonunion even though the major fragments were accurately apposed.

The reasons for nonunion are not known in all cases. In some it was caused by imperfect apposition of frag-

ments, largely due to insufficient internal rotation, and failure to check the position with lateral or vertical roentgenograms. In some cases too much dependence was placed on stereoscopic anteroposterior roentgenograms, which, although of great help, failed to give as accurate information about position as could have been obtained with lateral views taken with the Leonard curved cassette.⁴ An inadequate period of immobilization resulted in a few nonunions. In general these were weak, senile patients who were irritated by the treatment and failed to cooperate. In at least three and possibly in four cases, nonunion resulted from poor selection of Whitman treatment when roentgenograms showed marked arthritic change. In these the joint ankylosed after long immobilization, and the femoral neck, possibly with bone union, refractured when adduction was permitted after removal of the abduction plaster. Metabolism and blood chemistry studies in a few nonunion cases failed to show any cause for poor results.

"UNKNOWN CASES"

Twenty-one cases are reported as unknown because they were not followed a year after treatment. Thirteen were treated by the Whitman method. Of these,

Fig 3—Oblique fracture treated without sufficient internal rotation. Bony union resulted, but whole of femoral neck absorbed.

three undoubtedly developed nonunion. Eight patients were discharged with the expectation of bone union and two others were followed for six to eight months and when last seen appeared definitely to have bone union.

Eight of the unknown cases were treated by the traction and internal rotation method. Of these, three patients undoubtedly developed nonunion. Three were discharged with the expectation of bone union, and two others when last seen six or seven months later appeared to have bone union.

None of the foregoing twenty-one cases are classed in this report as other than "unknown."

The large number of twenty-one "unknown" is so great that it has seemed unwise to give percentages except for deaths.

SUMMARY OF END RESULT STUDY

Nineteen patients died in the hospital. Twenty-one were not followed long enough to be included and are classed as unknown. Sixty were followed one year or more. Of these, forty-four developed bone union, thirty-one by the Whitman treatment, and thirteen by

traction and internal rotation. Sixteen developed nonunion, twelve by the Whitman method and four by traction and internal rotation.

99 Bay State Road.

ABSTRACT OF DISCUSSION

DR. ARCHIBALD F. O'DONOGHUE, Sioux City, Iowa: The authors show a mortality of one out of five, principally in old persons. I don't believe that is going to be improved very much. They show a percentage of unions in patients who live of approximately 60, which isn't so bad and which possibly may

Fig 4—Oblique fracture with marked absorption of neck of femur resulting in bony union

be improved later. With some of the newer traction methods, especially the one devised by Roger Anderson, I think I have obtained better results than before, although the series has been too short to justify that as a definite assertion. There is one factor about a hip fracture which I have not heard discussed very much. Many papers are read on the treatment of hip fractures in the first three or four months but not many after that time. Advice is given to get patients up after the bone seems as solid as it is going to be. That is not easy to do. They don't handle a splint very well. A patient who has

Fig 5—Central oblique comminuted fracture resulting in bony union. Nonunion is common in this type of fracture.

a fracture of the hip and obtains a bony union and doesn't walk is as badly crippled as if the union hadn't taken place. Better results can be obtained if more attention is given after the plaster comes off. These patients are scared; their muscles are stiff and weak and flabby after a period of immobilization of three months. If these patients, when the casts are taken off, are placed daily in a water bath on a stretcher and allowed to exercise themselves, the period of hydrotherapy being gradually increased from five minutes to twenty-five or thirty minutes twice a day, they not only get their muscles in better shape but regain confidence in themselves and feel that they are going to be able to use the leg again. When the union is

⁴ Leonard, R. D. and George, A. W. A Cassette with a Convex Curve, *Am. J. Roentgenol* 28: 261 (Aug) 1932

strong enough to let them bear weight on the leg, they are afraid of crutches, afraid of hurting themselves over again. If they become dependent on crutches, it is difficult to get the crutches away from them. However, if they start walking in a runway where they can get hold of a rail with their hands, they gain confidence much better and are more likely to return to normal walking without using a crutch or cane than they would if they started with a cast or splint or crutches and were allowed to start themselves without any supervision. The Jones or Anderson tractor is going to help, but after-treatment carefully carried out along the lines I have mentioned is going to help more.

DR J. LAURENCE JONES, Kansas City, Mo. I am in almost complete agreement with the authors. One is frequently confronted with what is either a borderline or an actual pathologic fracture. The mechanism of injury seems to prove this. For example, the old lady standing in front of her mirror, combing her hair, suddenly turns and fractures her hip, in other cases the fracture occurs from minor injuries such as stubbing the toe. Case after case of this kind could not happen unless the condition was a borderline or actual pathologic fracture. Therefore I would like to add a bit of constructive criticism. In the treatment of all other fractures an orthopedic surgeon would not be satisfied unless both anteroposterior and lateral roentgenograms were made. The authors have spoken of the fact that they have taken such roentgenograms in many of these cases with the semicircular curved cassette described some years ago by Drs Leonard and George. For three years I have been attempting to perfect a technic for developing satisfactory lateral pictures. There will shortly be reported what I believe is an improved procedure. Lateral roentgenograms of the neck of the femur, up to this time, have been vaguely reminiscent of the lateral spine plates taken in the era before the use of the Bucky diaphragm. In these old pictures one could see that there were bones present but one didn't know just how many or where they were. The same condition has been true of lateral roentgenograms of the hip. They have been very hazy and, in addition, frequently the head has been thrown entirely off the plate. I shall consider only the method described by Drs Leonard and George, although there is another. In this procedure the tube was placed at the side with the film between the legs, and a semicircular curved cassette is used. In the method to be presented the head and neck can be placed regularly in the center of the film. The position used is with the legs abducted, and the tube is placed at the corresponding shoulder of the hip about to be filmed. The patient's thorax is then thrown out of the way by rotation and side bending. In other words, the picture is taken in the exact vertical position. I am now able to secure lateral roentgenograms of the hip that are about 70 per cent as clear as if a Bucky diaphragm had been used.

DR G. A. HENDON, Louisville, Ky. I wish to submit a plan of treatment that has served me excellently in a series of sixty-five cases, and that is by the introduction of what I call a key, which is made out of beef bone and which can be introduced in ten or fifteen minutes by an open operation. Nothing is exposed except the trochanter and there is no shock and no postoperative depression. I have never had a patient remain in bed more than four weeks. I do not use any kind of restraint. I do not use any kind of external immobilization. These patients are placed in bed and are permitted to assume whatever position seems to be the most compatible with their comfort. Patients have ranged from 62 to 87 years of age and I have had in that series of cases seven deaths, which could in no way be considered as the proximate result of either the operation or the injury.

DR LOUIS G. HOWARD, Boston. Dr. O'Donoghue was too generous in the percentages he gave. We purposely omitted percentages because we felt it was improper when there were so many unknown cases. We don't know how many instances of nonunion there were in that group. Dr. Jones mentioned that we used the Leonard cassette. We have not used it in the series reported in as many cases as he believes, because the series extends back over several years and stopped one year ago, and the Leonard cassette is a fairly recent contribution.

IIIP JOINT TUBERCULOSIS TREATED BY FUSION OPERATION

AN END RESULT STUDY OF ONE HUNDRED AND SEVENTY UNSELECTED CASES

HALFORD HALLOCK, M.D.

AND

JAMES W. TOUMEY JR., M.D.

NEW YORK

One hundred and seventy unselected cases of hip joint tuberculosis underwent operation at the New York Orthopaedic Dispensary and Hospital from April 1923 to July 1931 by the hip fusion method of Dr Russell A. Hibbs.¹ In this operation the anterior three-fourths of the greater trochanter, with its muscle and periosteal attachments intact, is transposed so as to make contact with the ilium above and the femur below and to secure at the same time periosteal continuity. It was hoped that, as in vertebral tuberculosis fusion

TABLE 1.—Deaths

Name	Age at Operation	Time of Death After Operation	Cause of Death
E. M.	21 years	9 months	Miliary tuberculosis
E. J.	12 years	8 months	Tuberculous meningitis
W. N.	19 years	2½ months	Tuberculous meningitis
G. K.	23 years	10 months	Miliary tuberculosis
F. B.	6 years	2 months	Pyelitis and nephritis, and probably disseminated tuberculosis
W. N.	3 years	4 hours	Shock
A. K.	23 years	At some unde- termined time after 8 months	Miliary tuberculosis and suppuration
J. O'B.	22 years	4 years	Pulmonary tuberculosis (?)
E. H.	6 years	3 years	Amyloidosis and broncho- pneumonia
E. K.	15 years	3 years	Unknown
T. P.	24 years	15 months	Amyloidosis
F. N.	10 years	2 years after fusion operation, 2 days after re- fusion operation	Undetermined
F. B.	9 years	4 years	Amyloidosis

Seven deaths occurred less than one year after operation, six deaths occurred more than one year after operation.

of the diseased bodies follows on that obtained by operation in the posterior elements, primary fusion would be of the transposed trochanter, ilium and femur, and ultimately of the diseased head and acetabulum. This hope has been realized, and an end result study of these cases is now reported.

RESULTS

Of the 170 patients, seven died within one year after operation. This leaves 163 who were available for examination one year or more after operation. All except one patient were roentgenographed at the hospital and were personally examined by experienced members of the staff. The excepted patient was examined and roentgenographed by a former member of the staff, now in Boston. The time of follow-up examination varied from one to eleven years inclusive and comprised a total of 888 and an average of 5.4 case years.

Fusion.—Of the 163 patients, 112, or 68.7 per cent, obtained a fusion by the first or primary operation. In

From the New York Orthopaedic Dispensary and Hospital.
Read before the Section on Orthopedic Surgery at the Eighty-Fifth Annual Session of the American Medical Association, Cleveland, June 13, 1934.

¹ Hibbs, R. A. *J. Bone & Joint Surg.* 8: 522 (July) 1926.

fifty-one cases, or 31.3 per cent, the operation failed. A second operation was performed in forty-one of the failures. Twenty-six of these (66⅔ per cent) were successful, thirteen were failures, one terminated fatally two days after operation, and in one the operation has been done too recently to show the result. Six cases required a third operation. Of these, four succeeded and two failed.

TABLE 2.—Failures According to Age Groups

Age of Patient	Number of Cases	Percentage of Failure
1 to 5 years inclusive.....	16	50
6 to 10 years inclusive.....	49	32.7
11 to 21 years inclusive.....	67	20.9
Over 21 years.....	31	38.7

If the successes of the reoperative cases are added to the 112 in which a fusion was obtained by primary operation, there are 142 hips, or 87.2 per cent, that are fused, and twenty-one, or 12.8 per cent, that are not. Fusion through the transposed trochanter was followed by fusion through the diseased area and gave an extremity that was stable and free from pain, and one that could be relied on for unrestricted weight bearing.

Sinuses.—Twenty-six (16.7 per cent) of 155 cases in which a note was made showed sinuses when last examined. In twenty-two of these fusion was present. Fourteen belonged to the group seen five years or more after operation.

Deaths.—Thirteen patients have died. Seven of the deaths occurred within one year after operation and six afterward. Two were operative deaths (table 1).

DETAILED STUDY

A detailed study of the relationship of fusion, as obtained by primary operation, to a number of various factors was made.

TABLE 3.—Distribution in Series and Failure Group of Factors Showing Significant Differences from the Mean Percentage Failure (31.3)

Factor	Number in Series	Number of Failures	Percentage of Failure	Percentage of Occurrence in Series	Percentage of Occurrence in Failure Group
1 to 5 years of age..	16	8	50	9.8	15.7
1 to 12 months' duration of symptoms	23	12	52.2	14.3	23.5
Faulty technic.....	92	38	41.3	60.1	77.5
Late fracture of mass.....	12	9	75	7.3	17.6
Early change of plaster.....	51	7	13.7	32.5	14.3

Factors occurring in significantly greater or less proportion in the failure group than in the whole series:

1. Faulty technic
2. Early plaster change (probably representing adequate immobilization)

Age Groups.—The cases were divided and the results studied in four groups (table 2). There was a relatively high percentage of failure (50) in the 1 to 5 year group, but this group included only sixteen cases and did not occur in much higher proportion in the failure group (16 per cent) than in the whole series (9.8 per cent) (table 3).

Duration of Symptoms.—The cases were classified in four groups based on duration of symptoms before operation (table 4). In the 1 to 12 months group there was a relatively high percentage of failure (52.2). The

group included, however, only twenty-three cases and did not occur in significantly higher proportion in the failures than in the whole series (24 and 14.3 per cent respectively, table 3). The standard for comparative analysis is given later.

Activity of Lesion.—An estimate of the degree of activity of the lesion was made in each case and was graded from 0 to 4 plus by a study of the preoperative roentgenograms and the conditions found at operation. If pus was found, a grading of 4 plus was arbitrarily given.

The cases were studied in two groups, one of lesser (0 to 2 plus) and one of greater (2½ to 4 plus) activity. There was practically an equal number in the two divisions and the percentage failures were 30 and 33.8 respectively. Of forty-seven cases with pus, fusion failed to occur in 29.8 per cent. Greater activity occurred as frequently in the whole series as in the failure group.

It appears therefore that statistically the degree of activity or the presence of pus has no appreciable effect

Fig. 1 (A. S., aged 6 years).—Proved case, before operation.

on the outcome as regards fusion or failure of fusion. It is felt, however, that in extremely active cases which can be kept under close observation operation might profitably be deferred for a short time and a preliminary attempt made by conservative means to secure some degree of subsidence of the activity.

TABLE 4.—Failure According to Duration of Symptoms Before Operation

Duration of Symptoms	Number of Cases	Percentage of Failure
1 to 12 months inclusive.....	23	52.2
1 to 5 years inclusive.....	57	23.9
5 to 10 years inclusive.....	47	23.8
Over 10 years.....	39	28.2

Preoperative Sinuses.—Twelve cases presented sinuses at operation and 41.6 per cent failed to fuse. This did not differ materially from the percentage failures of those which had never presented sinuses or from those which had previously presented sinuses that were closed at the time of operation. Sinuses cannot therefore be considered a contraindication to fusion.

Operative Technic.—A number of factors concerned in the transposition of the trochanteric mass were considered in relation to the success or failure of fusion.

Penetration and Fusion at the Ilium: By penetration is meant the depth to which the transposed mass of bone has entered sound bone in the ilium. It is measured

Fig. 2 (A. S.).—Result ten years after operation.

on the postoperative film by the distance of the end of the transplant from the nearest point of evident disease. Depending on the amount of penetration, the cases were divided into three groups, and the effect of this factor was studied from the standpoint of fusion of the mass to the ilium alone. In the 0 to one-fourth inch group there were eighty-seven cases, with a percentage failure of 28.7; in the one-fourth to one-half inch group, thirty-two, with a percentage failure of 9.4, and in the group with over one-half inch of penetration, thirty-

four, with a percentage failure of 5.9. No measurements could be made in ten cases.

The high incidence of failure in the group presenting poor penetration (0 to one-fourth inch) in comparison with the relatively low incidence in the other groups is of significance.

Femoral Contact and Fusion at the Femur: In a similar way the relationship of fusion at the femur to the extent of femoral contact of the transposed mass was studied, and it was found that the group of cases which had one-eighth inch or less of contact showed a much higher percentage of failure than those which had more (20 against 7.7 per cent).

Type of Transposed Mass: The cases were also studied in regard to the type of transposed mass. Forty-seven had a mass that consisted chiefly of trochanteric or cancellous bone, and 34 per cent failed; 103 cases had a mass in which the proportion of shaft or cortical bone was equal to or greater than the amount of trochanteric, and 31.3 per cent failed. No data were available in thirteen cases.

Fracture of the Transposed Mass at Operation: In six cases the transposed mass was inadvertently fractured at operation. Three fused and three (50 per cent) failed, two through the fracture site and one at the ilium.

Faulty Technic and Fusion: Combining three of the aforementioned factors, a study of the relationship of success or failure of fusion at any point to proper and faulty technic was made. Technic was considered to have been faulty in all cases that presented only from 0 to one-fourth inch of penetration, from 0 to one-eighth inch of femoral contact, or a fracture of the mass at operation. In this group 94.5 per cent of the cases showed poor penetration. The technic in ninety-two cases (60.1 per cent) was faulty and in 41.3 per cent it failed, chiefly at the ilium (28.7 per cent). In sixty-

one cases (39.9 per cent) the proper technic was used and in 18 per cent it failed. No data were available in ten cases. The marked difference in percentage failure between the two groups, which were both large, and the higher rate of failure of the faulty group in relation to the mean (31.3 per cent) are significant. Moreover, faulty technic occurred more frequently in the failure group (77.6 per cent) than in the whole series (60.1 per cent) (table 3).

Proof of Lesion.—In all but six cases microscopic study of tissue removed at operation was made, and in most cases a guinea-pig inoculation as well. One hundred and twenty-seven cases, or 77.9 per cent, were proved, by positive section, by positive guinea-pig test or by both to have been tuberculous. Proof was lacking in others, probably because extensive scarring in association with long-standing disease made it difficult to find diseased tissue, or because the active process was confined chiefly to the innermost recesses of the joint, which were not opened at the operation for fusion.

Postoperative Sinuses.—In fifty-six cases, or 34.2 per cent of the whole series, except for two in which no note was made, sinuses developed at some time after operation. This does not include the twelve patients who had sinuses at the time of operation. In twenty-two, or 39.3 per cent, the operation failed. Ninety-three cases remained without drainage and 25.8 per cent were failures. As noted previously, only 16.7 per cent of the series presented persisting sinuses at the follow-up examination.

First Plaster Change.—Fifty-one patients had their first plaster change within two weeks of operation, and

Fig. 3 (F. M., aged 6 years) —Proved case, before operation.

13.7 per cent of the operations were failures. One hundred and six had their first change more than two weeks after operation, usually at three months, and 39.6 per cent failed. This suggests that the low percentage of failure in the group changed early might have been due to a more adequate splinting of the hip by a better fitting plaster spica, put on leisurely and with care, after postoperative swelling had subsided and

before consolidation of newly formed callus had occurred.

Late Fracture of Transposed Mass.—Twelve cases showed roentgenologic evidence of a fracture through the transposed mass from three to fifteen months after operation. In only one was there any history of trauma. Of these twelve fractures, three ultimately united and fusion was secured; nine (75 per cent) failed to unite, and failure of fusion resulted. All twelve cases presented a portion of shaft bone in the transposed mass and in nine of them this was equal to or greater than the trochanteric portion. Ten of the fractures occurred through the cortical part and in two at the junction of the trochanteric and shaft portions. It is evident, therefore, that a late absorption fracture through the transposed mass is a possible and a serious complication, especially in cases presenting a shaft type of transposed mass.

Fusion at One Year After Operation and End Results.—At a twelve months period after operation

Fig. 4 (F. M.).—Result nine years after operation.

there were sixty-three cases in which clinical and roentgen examinations indicated the presence of fusion. Of these, one was later found not to be fused. Fifty-three were definitely not fused, and of these seventeen went on to fusion and thirty-six failed. In thirty-seven it was impossible to determine whether fusion was present or not. Thirty-three of these later showed unmistakable evidence of fusion and four of failure.

The Failure Group.—Fifty-one cases, or 31.3 per cent, failed to fuse by primary operation. The sites of nonunion are given in table 5.

Several cases failed in more than one place. For instance, of those failing at the ilium, five also failed at the center of the mass through late absorption fracture lines, and four at the femur. Of the thirty-one

TABLE 5.—Sites of Nonunion

Site	Number of Cases
Ilium	31
Femur	6
Center of mass	12
Epiphyseal line of mass.	2
Total.....	51

cases failing at the ilium, twenty-five, or 80.6 per cent, presented poor penetration.

The distribution in this group and in the whole series of the various factors that were found in the preceding study to be of definite significance in the matter of fusion are given in table 3.

Refusion Operations.—Forty-one patients had a refusion operation and in six of these a third procedure was necessary. The results have been given previously. At operation the defect was usually cleared of fibrous tissue and the space filled with bone chips. At times, large free grafts were used to bridge the space between the femur and the ilium. In twenty-five cases, or 62.5 per cent, active disease was found at the site of failure.

COMPARATIVE ANALYSIS OF FACTORS

In order to analyze comparatively the various factors in relation to fusion it was necessary to determine what should constitute significant differences of percentage in relation to numbers of cases. The following arbitrary standard was adopted:

1. If the group of cases under consideration comprised less than one tenth of the whole series, 20 per cent was taken to be the least amount of difference to which significance could be attached.

2. If the group comprised from one tenth to one half of the whole series, 15 per cent difference was required as a necessary minimum.

3. If the group comprised one half or more of the whole series, only a 10 per cent difference was considered requisite.

On this basis a definite difference in percentage failures in relation to the mean (31.3 per cent) was found in the following factors:

From 1 to 5 years of age.

From one to twelve months' duration of symptoms.

Faulty technic.

Late fracture of mass.

Early change of plaster.

But to be of statistical significance these factors must appear in definitely greater or less proportion in the failure group than in the whole series. This was determined, and it was found that in only the following two was this requirement satisfied:

1. Faulty technic.

2. Early change of plaster (which probably means adequate immobilization).

SUMMARY

1. The end results of 170 unselected cases of hip joint tuberculosis treated at the New York Orthopaedic Dispensary and Hospital from April 1923 to July 1931 by the hip fusion method of Dr. Russell A. Hibbs are reported. Seven patients died within one year after operation, leaving 163 who had follow-up examinations

Fig 7 (R. M., aged 4 years)—Proved case. Failure of fusion at the femur seven months after operation

of from one to eleven years inclusive, with an average of 5.4 case years. Seventy-seven and nine-tenths per cent were proved by microscopic examination or guinea-pig inoculation or by both to have been tuberculous.

2. By primary operation 112 cases, or 68.7 per cent, were fused; with secondary and in some instances tertiary procedures in forty-one cases, 142, or 87.2 per cent, were fused. Fusion through the transposed trochanter was followed by fusion through the diseased area and gave an extremity that was stable and free from pain, and that could be relied on for unrestricted weight bearing.

3. Thirteen deaths occurred, seven within a period of one year after operation and six afterward.

4. As determined by statistical analysis, the chief factors influencing fusion were found to be:

- (a) Faulty operative technic.
- (b) Adequate immobilization by replacing a probably fitting plaster by a snugly fitting one within two weeks after operation, after swelling had subsided and before consolidation of newly formed callus had occurred.

ABSTRACT OF DISCUSSION

DR. HENRY W. MEYERDING, Rochester, Minn.: I wish to congratulate the authors on presenting the large series of fusion operations for tuberculosis of the hip. I am impressed by the careful follow-up system as well as by the fact that 78 per cent of the cases were proved microscopically to be tuberculous. The results from surgical fusion, as shown in this series, are gratifying. I believe the pendulum will swing farther away from the conservative treatment, with the exception, possibly, of young children under 9 years of age. At the clinic the fusion operation is seldom used for young children. The duration of the disease is much longer and the average age much higher in the cases that I see. It should be accentuated

here that tuberculosis of the hip is a manifestation of a general disease, that the surgical treatment of a local manifestation is only a part of the treatment, and that general measures, such as usually are employed with tuberculosis, must be carried out carefully. In a series of forty-three cases reported at the International Orthopaedic Society meeting in London by Dr. Henderson, the results are practically the same, successful fusion having been obtained in about 90 per cent of cases. In that paper the different types of operation employed at the clinic to secure fusion were discussed, and it was pointed out that the combined operation, intra-articular and extra-articular, was found to be preferable. This may be due to the fact that experience at the clinic has been more with adults and with cases in which tuberculosis of the hip was of long standing.

DR. FRANK R. OBER, Boston: It is very interesting that these cases should be reported at this time, because Dr. Hibbs was probably the first to advocate the fusion of the hip in tuberculosis. The authors present many interesting facts. It seems to me, however, that the proportion of failures is quite high; namely, 31 per cent. The mortality rate also seems to me to be a little high. What is the reason for so many failures? It must be that the graft is not of sufficient size to support the femur against the body weight or that the disease is too acute, so that the graft melts away from the tuberculous process or the graft fractures. I think a better technic is one in which the ilium is exposed through the Smith-Petersen incision and a large mass of bone is turned down in strips, being previously split off the trochanter and the femur being bared anteriorly and posteriorly at the upper extremities. These strips connect the femur with the ilium and there is a veritable forest of bone in this neighborhood. Hips should not be fused when there is disease of the articular cartilage either in the head or in the acetabulum. Any hip with a few degrees of motion is always a liability. No patient with an active pulmonary lesion should have a fusion. Patients should not have fusions in the presence of pus. No fusion should ever be done until the patient is brought up to as nearly a perfect general physical condition as possible. The bony skeleton is then much better, the patient's resistance is better and the mortality rate will be lower.

DR. C. H. HEYMAN, Cleveland: It is not often that such a large number of end results is reported. The authors apparently believe in obtaining a bony ankylosis in order to obtain a cure and with that I am in agreement. The question arises as to the best method of obtaining this ankylosis. It is my experience that it is much easier to bring it about by resection of the joint cartilage. That, however, is not always done easily. I was under the impression that the operation, as originally proposed by Hibbs, was an extra-articular fusion. It is

Fig. 8 (R. M.).—Result six years after refusion operation and two months after subtrochanteric osteotomy for excessive flexion and abduction.

of no particular importance if one does get into the joint. It is necessary to get a good bony contact along the neck of the femur and penetration into the ilium, as the authors stated. I should like to ask the authors whether they perform the operation in the presence of a sinus. When there is a sinus there is a secondary infection. The principle of the operation is a bone graft, and graft operations are not done in the presence of an infection. I should also like to ask just what the lowest age limit is when they would operate. I have not done

many of these operations. In doing them I have been struck by the marked degree of bone atrophy involving the neck of the femur and the trochanter. This atrophy has sometimes been so extensive that one could cut the bone with a heavy pair of scissors. Does that make any practical difference? I have also encountered a technical difficulty in leaving the muscle attachments intact at the time of mobilizing the graft and turning it round. Sometimes I have been unable to drive this graft into the ilium, getting it flush with the neck of the femur, and at the same time leaving the muscle attachments intact. Is that of great importance? The authors emphasized the great importance of the early change of cast. That is something I cannot understand. It would seem, theoretically at least, that an early change of cast would entail manipulation and motion. It seems to me that the percentage of union would be higher by not changing the cast than if one did change it.

DR. JOSEPH S. BARR, Boston: I feel that all large orthopedic centers in the United States ought to lay their cards on the table regarding the percentage of failures and successes in fusion of tuberculosis of the hip. I reviewed 175 cases in the Massachusetts General Hospital in the ten year period from 1920 to 1930. I haven't the exact statistics here but the percentages were almost identical with those presented by Drs. Hallock and Toumey. The type of fusion varied with the operator—some intra-articular, some Hibbs and some a combination of the two or with the use of a graft from the ilium. We were presented a few years ago with the problem in the New England Peabody Home, in a group of children. After a review of the various methods of operation, we finally decided on a combination of technics and I want to report the first twenty cases in which that method was used. In brief, the results were as follows: There were nineteen successes by the first operation and one failure, since fused by a second operation. There were no deaths, no sepsis, no draining sinuses. The exposure for the operation was through the Smith-Petersen incision. The head and neck of the femur were denuded of cartilage and cortical bone. The trochanter was partially osteotomized and flaps were levered out anteriorly, laterally and posteriorly without being completely detached. Long grafts were then cut from the outer table of the ilium, each graft about 3 inches long and half an inch wide. They were then laid parallel to the neck of the femur, the upper end of the graft in contact with cancellous bone of the ilium. The lower end of each graft was attached firmly in the trochanteric slots. The chief advantage of this method is that it gives one a very flexible graft, which cannot be displaced by moderate changes in position of the hip, and which tends to unite in a solid bony fusion in an extraordinarily short time, some of the cases being solidly fused within three months after the operation.

DR. HALFORO HALLOCK, New York: Dr. Toumey and I believe that general care is of importance. After operation, or in instances in which surgery is to be postponed, cases are sent to the country branch for general treatment. The fusion operation is extra-articular in the sense that the innermost recesses of the joint are not entered. The capsule is opened superiorly over the femoral neck, but that is all. No attempt is made to excise large amounts of diseased tissue, because it may increase the danger of possible spread and generalization and because it is not necessary. We have found that, if bony fusion is obtained, nature will take care of the disease. Sixty-nine per cent of successes is a good average for a large series of a major surgical condition. Thirty-one per cent failure, by primary operation, however, has given us concern; and it was for the purpose of finding out the reasons for failure that this study was begun five years ago. Statistically, the only significant factors were faulty technic and failure to change the first plaster early after operation. The death rate in this series, 8.6 per cent, is slightly higher than that in 150 cases reported from the Hospital for Ruptured and Crippled by Dr. Gibney in 1898 but lower than that in 150 cases treated by traction splint and heliotherapy at the Country Branch of the New York Orthopedic Hospital, reported by Smith and Watters in 1928. These rates were respectively 7.3 and 16 per cent. Joint cartilage is not resected, as to do so would further open up diseased areas and prolong the time of opera-

tion. We do operate in the presence of sinuses, for apparently they do not make any difference in the outcome. The youngest patient was a child of 1 year, and he obtained a fusion. Atrophy of the trochanter has not had any demonstrable effect. No difference of percentage failure was found in cases that presented marked degrees of decalcification of hip and trochanter. The muscle attachment is left intact if possible; but lately we have tried several free trochanteric masses, and fusions were obtained without difficulty. Plaster support is maintained from six to twelve months, with an average of about nine months.

INTESTINAL TUBERCULOSIS

PATHOLOGIC AND ROENTGENOLOGIC OBSERVATIONS

RUSSELL S. BOLES, M.D.

AND

JACOB GERSHON-COHEN, M.D.

PHILADELPHIA

It is our purpose in this paper to present certain observations on intestinal tuberculosis based on 1,000 consecutive autopsies performed at the Philadelphia General Hospital during the last six months of 1933, and to describe an x-ray procedure which we hope may be helpful in the clinical diagnosis of the disease.

TABLE 1.—Analysis of 1,000 Consecutive Autopsies

Pulmonary Tuberculosis, Healed and Active	Intestinal Tuberculosis	
	Ulcerative	Hyperplastic
Present 226, or 22%	63, or 28%	0
Absent 774, or 77%	0	0

TABLE 2.—Analysis of Pulmonary Tuberculosis Group

Tuberculosis of the lungs.....	226 cases
Fibro-ulcerative cavernous.....	105 cases, or 46%
Fibroid.....	83 cases, or 38%
Exudative.....	22 cases, or 10%
Miliary.....	12 cases, or 5%
Tuberculous pneumonia.....	2 cases, or 1%

It is generally conceded that tuberculous ulceration of the intestine is a frequent complication of pulmonary tuberculosis. From an analysis of the literature it is easy to deduce that there are no symptoms or physical signs that point conclusively toward intestinal involvement, whether it is early or far advanced. In many instances it would appear that symptoms and physical signs may be indefinite even in the presence of advanced intestinal disease. Clinically, therefore, the diagnosis is seldom made with any degree of certainty, although it is presumed to exist in many cases.

Numerous pathologic studies show a consistently high incidence of intestinal tuberculosis associated with pulmonary tuberculosis, the incidence varying from 50 to 90 per cent.

Few of the pathologic reports in the literature show any correlation between the types of pulmonary disease and the intestinal process, and still fewer show any correlation between the pulmonary and the intestinal types of disease with associated tuberculosis of other abdominal organs.

Read before the Section on Gastro-Enterology and Proctology at the Eighty-Fifth Annual Session of the American Medical Association, Cleveland, June 13, 1934.

From the Medical and Pathological Departments of the Philadelphia General Hospital and the X-Ray Department of the Eagleville Sanatorium, Eagleville, Pa.

The following analysis of the autopsies studied was undertaken in order to determine (1) if tuberculosis of the intestine, whether hyperplastic or ulcerative, occurred more frequently than is suspected in the absence of pulmonary tuberculosis; (2) its incidence and relation to the type of pulmonary tuberculosis, and (3) the incidence of associated tuberculous disease of

A study of the relation of the type of pulmonary disease to sex and race clearly indicates that fibroid pulmonary lesions predominate in white males, that fibro-ulcerative cavernous lesions are about equally distributed, and that both exudative and miliary pulmonary lesions predominate in Negro males. While the age incidence of this group was not studied, the low incidence of fibroid lesions in the Negro race would suggest that Negroes succumb to it sooner than white people.

A study of the relation of the type of pulmonary lesion to intestinal ulceration shows conclusively that intestinal ulceration does not occur in the healed fibroid cases, eighty-five of the latter being encountered without

other abdominal viscera. For these reasons, consecutive autopsies were analyzed regardless of the cause of death.

Of the 1,000 autopsies studied, tuberculosis of the lungs was found in 226 cases, or 23 per cent. No evidence of it was found in 774 cases. This comparatively low incidence of pulmonary tuberculosis in such a large general group can probably be attributed to the fact that serial histologic sections were not made of lungs that appeared grossly normal and therefore would not include cases with evidence of healed primary lesions in the lungs or tracheobronchial nodes. Cases presenting healed apical lesions due to secondary infection will be referred to as chronic fibroid tuberculosis. In the entire 774 negative pulmonary cases no evidence of tuberculosis of the intestine, either hyperplastic or ulcer-

TABLE 5.—Relation of Fibro-Ulcerative Cavernous Tuberculosis to Sex, Age and Race

a single instance of such a complication. The highest incidence of intestinal ulceration was observed in the fibro-ulcerative cavernous type of pulmonary disease; i e., in fifty-nine of 105 cases, or 56 per cent. The incidence was next highest in the exudative pulmonary lesion; namely, in four, or 18 per cent. In twelve miliary cases of pulmonary tuberculosis, intestinal ulceration was not seen in a single case, although, as will

TABLE 4.—Relation of Pulmonary Tuberculosis to Ulcerative Intestinal Tuberculosis

Type Pulmonary Tuberculosis	Ulcerative Intestinal Tuberculosis

	226 cases	63 cases 28%

ative, was found. In the 226 cases of healed and active pulmonary tuberculosis, an ulcerative type of intestinal lesion occurred in sixty-three cases, or 28 per cent. Primary hyperplastic tuberculosis or tuberculoma of the large bowel was not observed in the 1,000 autopsies, and it must be regarded, therefore, as a most infrequent variety of intestinal tuberculosis in adults. It may be more common in children, very few of whom were included in this study.

Of the 226 cases of pulmonary tuberculosis, the type and incidence of lung lesions were as follows: fibro-ulcerative cavernous, 105 cases, or 46 per cent; chronic fibroid, eighty-five cases, or 38 per cent; exudative, twenty-two cases, or 10 per cent; miliary, twelve cases, or 5 per cent, and only two, or 1 per cent, were classified as tuberculous pneumonia. The latter figure is of interest, considering the frequency with which such a clinical diagnosis is made.

TABLE 6.—Relation of the Type of Pulmonary Tuberculosis to the Site of Intestinal Ulceration*

Pulmonary Tuberculosis	Ileum	Cecum	Ascending Colon	Transverse Colon	Descending Colon	Rectum
Fibroid	85	0	0	0	0	0

Exudative	22	3	1	1	1	1
Miliary	12	0	0	0	0	0
Tuberculous pneumonia ..	2	0	0	0	0	0

* Intestinal ulceration predominates in fibro ulcerative cavernous pulmonary disease. Incidence of ulceration is highest in ileum and becomes decreasingly frequent from the ileum toward the rectum. Intestinal ulceration is conspicuously absent in the fibroid and miliary types of pulmonary lesions.

be shown later, a miliary lesion of the serosa of the intestine was not infrequently noted. Neither of the two cases of tuberculous pneumonia showed any intestinal ulceration. While the sputum was not examined in all cases for various reasons, it is of interest that it was found positive in forty-four of sixty-three cases of intestinal ulceration, or 60 per cent. It is plainly evident that the open ulcerative pulmonary lesions, most if not all of which at one time or another present positive sputum, are the ones most apt to be accompanied

by intestinal ulceration, so much so that one could almost feel safe in saying "No intestinal ulceration without pulmonary ulceration." It is of further significance in this connection that the miliary cases of pulmonary tuberculosis which are not open and do not present positive sputum likewise do not show intestinal ulceration. This would appear to support the contention in some circles that intestinal mucosal lesions are caused by swallowed tubercle bacilli or enterogenous infection and that intestinal serosal lesions, as observed in the miliary type of pulmonary lesion, are probably due to blood-borne tubercle bacilli or hematogenous infection. The more frequent association of generalized visceral tuberculosis in the miliary cases than in the ulcerative cases, as will be shown, also supports this view. However, whether intestinal tuberculosis is due to infection being carried by the sputum, blood stream or lymphatics is a question that must still be determined.

Since it was only in the fibro-ulcerative cavernous type of pulmonary disease that intestinal ulceration was observed, it is of interest to study this group further. It will be noted that ulceration of the intestine developed most frequently in women between 20 and 40 years of age, and especially in the Negro race. The patients without intestinal ulceration definitely exhibited a tendency to live longer, regardless of sex or race.

It was previously mentioned that comparatively little data are available on the relation of the type of pulmonary lesion to intestinal ulceration, especially as regards the location of the intestinal lesion. An analysis of this relation demonstrated that while intestinal ulceration again occurred most frequently in the fibro-ulcerative cavernous group of pulmonary lesions, the incidence of ulceration was highest in the ileum. Almost as frequently it was found in the cecum, and then a very marked decline in the frequency of ulceration was observed in each successive distal segment of the bowel. The latter part of this observation confirms what has been previously recognized. No attempt is made to explain the high incidence of ileocecal ulceration. It has been suggested that it is due to a combination of such factors as stasis, a rich supply of blood vessels and lymphatic tissue, and a high degree of absorption in this area.

It is frequently stated that healing of tuberculous ulceration in the intestine may take place regardless

were not made in our cases, but gross evidence of a healed ulcer was seen in only one case. Absence of healing has been attributed to the fact that intestinal ulceration is a terminal complication and consequently the patients do not live long enough for healing to take place. That it may be a complication of early pulmonary tuberculosis is attested by finding tuberculous ulceration of the ileum in four of the twenty-two cases in the exudative group; two of the patients had died from tuberculous meningitis, one from tuberculous pericarditis, and one from myocarditis and lead poisoning. Such evidence would seem to indicate that intestinal ulceration is not necessarily a terminal complication but is simply not recognized, as a rule, until the patient is in an advanced stage of pulmonary and intestinal disease.

A study of the incidence of tuberculosis of the abdominal viscera in cases with and without intestinal ulceration and its relation to the type of pulmonary lesion demonstrates that there is a strong probability of the viscera being involved in cases of ulcerative pulmonary tuberculosis as well as in miliary tuberculosis.

Fig. 1.—A, single contrast enema; B, double contrast enema of an excised colon. The patient had moderate pulmonary ulcerative tuberculosis and minimal tuberculous ulceration of the terminal ileum and cecum. The irregularity of the cecal margin is slight in the single contrast enema film, whereas in the double contrast enema film marked mottling of the mucosa of the cecum is seen, as a result of the uneven distribution of the coating of barium on the ulcerated mucosa. Roentgen appearances of ulcerated intestinal mucosa were studied by this method on excised colons obtained by autopsies.

The viscera most frequently involved were the spleen, the liver and the kidneys. The probability of visceral tuberculosis is shown to be greatly increased in the presence of intestinal ulceration. Healed miliary tubercles of various abdominal viscera were occasionally seen in cases showing a healed pulmonary lesion.

A number of practical considerations may be evolved from this study of 1,000 autopsies. In view of the multiple pathologic lesions present in patients who die from tuberculosis, it is not difficult to understand why the symptomatology of the disease is so obscure. This is especially the case with intestinal tuberculosis, in which one must consider that not only are several segments of the intestinal tract often affected, but in addition there is a substantial probability that other abdominal viscera, especially the spleen, liver, kidneys, peritoneum and suprarenals, are likewise involved.

When one considers the widespread distribution of the disease it becomes at once apparent that such a surgical measure as resection of a tuberculous ulcerated area of the bowel is highly impractical.

TABLE 7.—*Tuberculosis of Abdominal Viscera**

	With Intestinal Ulceration (63 Cases)	Without Intestinal Ulceration (163 Cases)

* The probability of associated tuberculosis in other abdominal organs is greatly increased in the presence of intestinal ulceration. The spleen, liver and kidneys are the organs most frequently involved.

of the activity of the pulmonary lesion and in the presence of progressive ulceration elsewhere in the bowel. Detailed examinations for evidence of healing

As regards primary hyperplastic tuberculosis or tuberculoma of the bowel, one must consider in the differential clinical diagnosis that it rarely occurs, whereas carcinoma, which it may simulate, is not unusual in the tuberculous subject.

The various complications and associated diseases revealed in this analysis cannot be presented at this time. From a practical standpoint it is of interest to note that perforated tuberculous ulcers were rarely found, while peptic ulcer, nontuberculous appendicitis and diverticulitis, all with and without perforation, were not infrequently noted as complications of pulmonary tuberculosis. Among the more commonly noted associated diseases were those of the cardiovascular-renal systems, chronic cholecystitis and cholelithiasis, and cirrhosis of the liver, all of which must be kept in mind in the clinical appraisal of the cases under discussion.

ROENTGEN DIAGNOSIS

As an important aid in the diagnosis of ileocecal tuberculosis, we would recommend the double contrast enema. The barium meal method is more generally used

Fig. 2.—A, single contrast enema; B, double contrast enema showing minimal cecal tuberculosis. The mottling of the barium coating on the ulcerated mucosa of the cecum is clearly seen in the double contrast films.

at present following Sampson and Brown's work, but its reliability depends on such indirect signs as segmental irritability and hypermotility. The double contrast enema, in addition to retaining these signs, provides an accurate demonstration of the actual morbid anatomic changes of the diseased segments of the bowel.

It has been exceedingly difficult to obtain verification, by either operation or autopsy, of early lesions, diagnosed roentgenographically. An opportunity for checking the diagnosis, however, was afforded by the postmortem examination of patients who had died in the terminal stages of tuberculosis, many of whom had early lesions in one or another segment of the colon, usually distal to the advanced lesions in the ileocecal areas. From a comparison of the roentgen and post-mortem observations in these distal segments in which early lesions were present, some fairly reliable impression was gained of the value of the double contrast studies.

The following technic is based on an experience of more than five years of routine use at Eagleville Sanatorium, during which we have had no untoward effects:

An ordinary enema of barium sulphate and warm water is first given and the usual roentgen studies are made, the quantity

of injecta being noted. The second roentgen study, which is made after evacuation of the injecta, includes notation of the approximate amount of residue and its distribution. The third phase of the study is carried out by inflating the colon with air. A ball valve Politzer bag of known air capacity is used. No special rectal nozzle is used, since the ordinary adult size hard rubber nozzle is satisfactory except in the presence of a fistula or an otherwise damaged rectal sphincter. The colon is filled with air under fluoroscopic control. Overdistention is avoided by controlling the actual amount of air injected, which should never exceed the amount of opaque injecta. When these precautions are heeded, examination is no more objectionable to the patient than is the simple barium enema.

The roentgen diagnosis of early lesions is primarily based on abnormal outlines and marginal irregularities of the colon. In the affected areas a mosaic appearance of the mucosal surfaces is seen in the double contrast films. This mottling of the thin barium coating on the diseased mucosa may be seen in the very early stages of ulceration, sometimes before there are appreciable irregularities in the outline of the colon. The secondary signs resulting from irritability and hypermotility of the involved areas that may be observed fluoroscopically strengthen the diagnosis. The older lesions may be diagnosed more readily than the early lesions because they are larger and more widely distributed and show an exaggeration of the changes in the colonic margins and mucosa, which are strikingly discernible in the double contrast films. Finally, the double contrast enema is superior to the barium meal study because it gives fuller visualization of the degree and extent of tuberculous involvement, is less expensive, takes less time, and is not so tiring to the patient.

The barium meal is still the examination of choice to detect stenosis in the jejunum and ileum, since it is the only practical way of filling the small intestine with opaque material.

If we are correct in assuming that the double contrast enema examination will lead to a diagnosis of early minimal lesions, it is hoped that better therapeutic results will follow in that large group of cases presenting chronic ulcerative cavernous pulmonary tuberculosis in which this complication arises.

SUMMARY AND CONCLUSION

1. One thousand consecutive autopsies at the Philadelphia General Hospital were analyzed to show the incidence of intestinal tuberculosis and its relation to pulmonary tuberculosis.

2. Ulcerative intestinal tuberculosis was shown to have its highest incidence in cases of fibro-ulcerative cavernous pulmonary tuberculosis. It was so confined to this group that one might suspect that there is no intestinal ulceration without pulmonary ulceration. It was shown to occur in cases of early or exudative pulmonary tuberculosis, in which, however, it had its lowest incidence (18 per cent). It occurred more frequently in women of the Negro race between 20 and 40 years of age. It was not observed in any case of chronic fibroid or miliary tuberculosis.

3. Primary hyperplastic tuberculosis or tuberculoma of the bowel was not observed in any case.

4. Such nontuberculous intestinal lesions as carcinoma, peptic ulcer, appendicitis and diverticulitis, all with and without perforation, were associated with pulmonary tuberculosis.

5. Cardiovascular-renal disease, chronic cholecystitis, cholelithiasis, and cirrhosis of the liver were commonly noted diseases associated with pulmonary tuberculosis with and without intestinal ulceration.

6. In view of the uncertainty of the symptoms and physical signs of intestinal tuberculosis, we believe that a strong inferential diagnosis of the disease can be made when one considers it in its relation to the various types of pulmonary tuberculosis and as a result of evidence secured by the double contrast barium enema.

Rittenhouse Plaza.

ABSTRACT OF DISCUSSION

DR. IRVING GRAY, Brooklyn: The opportunity to study the incidence of tuberculosis of the gastro-intestinal tract clinically and at the autopsy table was afforded me at the Sea View Hospital, Staten Island, where there are more than 1,500 patients with pulmonary tuberculosis. The most frequent site of the

Fig. 1.—Anteroposterior view showing textile bobbin in esophagus.

Fig. 2.—The inflammatory mass surrounding the bobbin is visible in the lateral view.

Fig. 3.—Appearance after the ingestion of opaque oil. This shows that the upper lumen of the esophagus is separated from the bobbin by 1 cm. of scar tissue.

intestinal lesion was the terminal ileum. Old and fresh mucosal ulcerations were occasionally noted within the same segment of the intestine. In the severe cases of the caseous pneumonic type, extensive ulcerations of the small bowel have been noted sometimes involving the entire bowel as high as the upper coils of the jejunum. Tuberculosis in the colon is not common. The ileocecal junction is the most frequent site of tuberculosis of the gastro-intestinal tract. The presence of tuberculosis of the colon is distinctly diminished as one proceeds from the cecum to the sigmoid. The double contrast barium enema, as suggested by Dr. Boles and Dr. Gershon-Cohen, is of value in the type of case in which disease of the colon is suspected. As a diagnostic method, it offers more aid than the ordinary contrast enema. The authors have called attention to the fact that there is no parallel between clinical symptoms and the extensive pathologic change in the bowel. Gastro-intestinal tuberculosis is a common complication of pulmonary tuberculosis and I agree that it is due to the swallowing of tubercle bacilli and not to a blood stream infection. The authors are probably correct when they state that the involvement of the serosa is due to a blood stream infection. In my experience, intestinal tuberculosis occurs somewhat more frequently in the female than in the male. This may be explained in part by studies showing the gastric acidity to be lower in the female than in the male. As Van Sandt and others have shown, there is a tendency in all the groups for gastric acidity to be lower in the female than in the male.

Clinical Notes, Suggestions and New Instruments

SHARP DISSECTION THROUGH AN ESOPHAGOSCOPE: REMOVAL UNDER BIPLANE FLUOROSCOPE OF BOBBIN IN ESOPHAGUS

MURDOCK EQUEN, M.D., ATLANTA, GA.

The prompt removal of a metallic object caught in the esophagus rarely presents difficulties to a surgeon with modern training in this specialty. When such an object has been impacted over a long period, however, the resultant scarring complicates the issue.

REPORT OF CASE

A girl, aged 7 years, was referred to me from another state, Jan. 10, 1933, with the following history: In the summer of 1930 she had swallowed a textile machine bobbin. Although she duly reported this fact to her parents, no particular attention was paid to her story until after many months they noticed that she was having difficulty in swallowing and that she had lost weight and strength. Two years after the accident the presence of the bobbin in the upper part of the esophagus was proved by a roentgenogram. Dr. N. E. Sellers of Anniston, Ala.,

performed a gastrostomy to prevent starvation and dehydration. Her general condition growing steadily worse, in spite of the operation, six months later she was brought to Atlanta.

At the first endoscopic examination it was found that the esophagus, markedly dilated for 5 cm., was then completely obstructed with dense scar tissue, which showed no sign of the lumen. The condition of the esophagus was checked by a roentgenogram taken after she had swallowed some opaque oil. The plate revealed that the scar tissue separating the upper lumen of the esophagus from the bobbin was 1 cm. thick. Since it was impossible to find any opening through this, it was out of the question to attempt to dilate the esophagus by ordinary measures. To restore a lumen and to remove the bobbin therefore required, in spite of the risk, actual cutting through the scar tissue. Laryngoscopic knives were too short to be used through the esophagoscope, so a small Bard-Parker handle was cut down and fused on a metal rod; a suitable blade completed a satisfactory knife.

Under the guidance of Dr. W. F. Lake by means of a biplane fluoroscope, I cut through scar tissue until the bobbin was reached. It was then grasped with bronchoscopic forceps, but it was so firmly embedded that additional dissection was necessary to dislodge it. Moderate hemorrhage was controlled by the application of epinephrine sponges with pressure. On account of the resistance of the proximal scar tissue, I finally decided that it was safer to push the bobbin through the rela-

tively normal distal esophagus. After working it into the stomach, Dr. G. W. Fuller grasped it with forceps inserted through the gastrostomy wound and succeeded in removing it in spite of the disproportion between the size of the bobbin and the size of the opening. Dr. Fuller then passed a string of heavy silk to the forceps, which had extruded the bobbin through the cardia, and this string was drawn back up through the esophagus. The string was left in place to keep the esophagus open by retrograde dilation.

Convalescence was slow but uneventful, and the patient was allowed to leave the hospital, May 8. At the time of dismissal she was able to drink freely, although she was still experiencing a little trouble with a soft diet. Her parents were instructed to bring her back for further dilations in the hope of restoring the normal function of the esophagus, but so far they have not done so.

COMMENT

This case serves to illustrate again the importance of prompt investigation when a child says that he has swallowed or aspirated some unusual object. If this child had been examined even within a few weeks of the time she swallowed the bobbin, its removal would have been a simple procedure devoid of danger. The case further serves to illustrate the necessity for fluoroscopic guidance in two planes when an object that cannot be seen by direct vision must be removed endoscopically. It would have been impossible to locate the bobbin, to cut around it or to push it into the stomach without fluoroscopic guidance.

The case has been of the greatest interest to me in demonstrating how great an insult the esophagus can stand.

PERITONEAL REACTION TO LIQUID PETROLATUM

JACK C. NORRIS, M.D., AND T. C. DAVISON, M.D., ATLANTA, GA.

For many years surgeons have hoped for a method of procedure, or a remedy, that would prevent the occurrence of adhesions in the peritoneal cavity. In the past some of the

Fig. 1 (case 1).—General chronic inflammatory reaction occurring in omentum. Note vacuolated spaces surrounded by elongated giant cells; also note groups of giant cells. Elsewhere are the lymphocytes, fibroblasts and other cells.

substances that have been used are petrolatum, iodine and petrolatum, and liquid petrolatum. This paper does not deal with the efficiency of those remedies, but it presents a report

of interesting changes of an inflammatory nature that have occurred in the peritoneal cavities of two patients.

In August 1934 Mrs. G. W., aged 53, was undergoing an abdominal operation at Grady Hospital. The surgeon (T. C. D.) observed a quantity of peculiar chylus-like fluid in the peritoneal cavity. Likewise there was considerable fatty necrosis of the omentum. On several areas of the jejunum there were

Fig. 2 (case 2).—Vacuoles of varying size with the giant cells about them and the specific inflammatory reaction as described in the paper. The giant cells are of a foreign body type and in some places are found to be completely encircling the oil globules just as though the reaction was one of an inclusion body type.

small, elevated, irregular in size, grayish white granular nodules, which tended to spread. When these nodulations were removed, they left a bleeding serosal surface. Similar nodulations were present in the omentum and were removed. Frozen sections of the tissue, examined by the pathologist (J. C. N.), revealed the lesions to be of a chronic inflammatory type.

Further examination of the gross specimens by the pathologist showed the nodulations to be grayish white, irregular in size and very firm, with some elasticity. On pressure, small transparent globules were expressed from them, yet these globules were not at that time recognized. The paraffin sections showed a generalized chronic inflammatory reaction characterized by fibrotic overgrowth, areas of round cell collection, small new formed vessels, few polymorphonuclears, small necrotic areas and large vacuolated spaces, which were surrounded by elongated foreign body giant cells. In some parts of the section the giant cells seemed to aggregate; in others they elongated themselves and had become crescent shaped as they circled fat vacuoles. The microscopic appearance was considered one of foreign body reaction. It was later ascertained by the surgeon (T. C. D.) that the patient had previously been operated on in April 1934 for intestinal adhesions, at which time 4 ounces (120 cc.) or more of liquid petrolatum had been placed in the abdominal cavity in the hope that future adhesions would be prevented. This information was important and these facts, with pathologic consultations as supporting evidence, convinced us that the nodules in the peritoneal cavity of the patient were caused by liquid petrolatum. As a matter of general information and record the history is herewith briefly presented:

CASE 1.—Mrs. G. W., age 53, admitted, Aug. 13, 1934, for pain in the abdomen, had undergone two operations prior to admission. The first operation was performed in October 1933, when a cystic ovary was removed. In April 1934 a second operation was done and numerous adhesions were found. Before the second operation she complained of severe abdominal pains, which were augmented after meals, though the pain was continuous in character. After eating, distention and eructation were sequelae along with the increased pain. The second operation brought no relief, the symptoms becoming increasingly more severe.

The patient was malnourished and emaciated. The abdomen was somewhat distended, though not markedly. There was some doubt as to whether or not fluid was present, and if so there was only a small amount. Two scars were present as evidence of previous operations. Abdominal tenderness was elicited throughout.

Chemical examination of the blood, a blood count and urinalysis gave negative results. The Wassermann reaction was negative.

Drainage from the lesser and greater peritoneal cavity was done. General supporting measures were instituted. The results were excellent, with rapid recovery of the patient.

At a later date, while discussing the interesting peritoneal reaction, Dr. Davison recalled another case:

CASE 2.—A woman, aged 17, single, complained of pain in a previous abdominal scar. She had been operated on in 1932 for cystic oophoritis and abdominal adhesions. She had had a ruptured appendix in 1930. These operations had produced considerable scarring. Oil was poured in the abdominal cavity in 1932 following the second operation.

In 1934 she came to the hospital complaining of a localized pain in the extreme end of the previous incision. This pain was intensified by walking, riding and dancing, and was occasionally accompanied by nausea but no vomiting.

Examination led to the impression of hernia or adhesions. Blood and urine analyses were negative, including a Wassermann test and cellular study.

The diagnosis was made of recurrent abdominal adhesions involving the previous wound scars. Operation was performed (T. C. D.), and the surgeon observed a mass 1 inch in diameter attached to the peritoneal wall and lower end of the incision; elsewhere throughout the parietal and visceral wall were innumerable nodules varying in size from 1 mm. to 2 cm. Several were removed for histologic study. They resembled malignant nodules and were thought to be sarcomatous metastases. Recovery was uneventful, and at present the patient has had no return of symptoms.

In this patient the nodules were similar in color and consistency to those in the first patient yet were larger and more diffuse and resembled malignant metastases. The pathologist reported the lesion as one of sarcoma. The patient had an uneventful operative course and appeared quite well when released from observation. Four roentgen treatments were given. She continued in good health and this fact seemed inconsistent with the previous diagnosis of general sarcomatosis. Another study of the tissue sections showed an inflammatory reaction almost identical with the pathologic changes observed in case 1. The photomicrographs illustrate the tissue changes.

Since the observation of these lesions, more cases of the same type are being recognized, and it seems that many surgeons have been using liquid petrolatum to prevent adhesions.

SUMMARY AND CONCLUSIONS

1. Two patients had peculiar abdominal symptoms. Liquid petrolatum had previously been instilled in the peritoneal cavity of each patient.

2. Later operations in each case disclosed a chronic specific type of inflammation in which the histologic reaction of the two were similar.

3. We feel with the facts at hand at present that liquid petrolatum is responsible in each instance for the inflammatory reaction in the peritoneal cavities.

4. Based on the experiences and observations so far as observed and reported, we feel that liquid petrolatum should not be placed in the peritoneal cavity.

Distinction Between Science and Art.—Art looks to symptoms and occasions, science to evidence and cause. Art is therapeutic and prognostic, science is diagnostic. Art has a method whereas science has a system. Art looks in the main to function while science looks to structure. Art runs for the stomach pump while science studies the phenomena of poisoning. Art submits to be ignorant of much while science submits to be ignorant of nothing. Art acts while science speaks.—Blumer, George: Some Discursive Remarks on Bed-side Diagnosis, *Yale J. Biol. & Med.* 6:571 (July) 1934.

Special Article

ALTHOUGH A NUMBER OF BACTERIOPHAGE AND ANTIVIRUS PRODUCTS HAVE APPEARED ON THE MARKET DURING THE PAST SIX YEARS, RELATIVELY FEW HAVE BEEN SUBMITTED TO THE COUNCIL ON PHARMACY AND CHEMISTRY. NONE HAVE BEEN ACCEPTED FOR INCLUSION IN NEW AND NONOFFICIAL REMEDIES. INQUIRIES FROM PHYSICIANS, HOWEVER, AND THE ADVERTISEMENTS OF MANUFACTURERS INDICATE THAT THE EXPLOITATION OF THESE PREPARATIONS IS SUFFICIENT TO WARRANT THE PUBLICATION OF A REPORT ON THEM. AS THE SUBJECT IS RELATIVELY NEW AND OBSCURE, AND AS THE PUBLISHED ACCOUNTS OF BACTERIOPHAGE THERAPY ARE CONFLICTING, IT IS OBVIOUS THAT A REPORT LIMITED TO COMMENTS ON THE COMMERCIAL PREPARATIONS WOULD HAVE ONLY A RESTRICTED USEFULNESS. BELIEVING THAT PHYSICIANS DESIRE A MORE EXTENSIVE PRESENTATION OF INFORMATION ABOUT BACTERIOPHAGE AND THE PRINCIPLES AND POSSIBILITIES OF BACTERIOPHAGE THERAPY, THE COUNCIL ON PHARMACY AND CHEMISTRY HAS AUTHORIZED THE PUBLICATION OF THIS REVIEW. IN ADOPTING THIS REPORT THE COUNCIL EXPRESSED APPRECIATION OF THE EXCELLENT WORK OF DRs. EATON AND BAYNE-JONES. THE FIRST PART OF THIS REVIEW APPEARED IN THE JOURNAL LAST WEEK; IT WILL BE CONCLUDED IN THE NEXT ISSUE.

PAUL NICHOLAS LEECH, Secretary.

BACTERIOPHAGE THERAPY

REVIEW OF THE PRINCIPLES AND RESULTS OF THE USE OF BACTERIOPHAGE IN THE TREATMENT OF INFECTIONS

MONROE D. EATON, M.D.

AND

STANHOPE BAYNE-JONES, M.D.

NEW HAVEN, CONN.

(Continued from page 1776)

Bacteriophage Treatment in Other Suppurative Conditions.—The various accounts of the treatment of suppurative conditions with bacteriophage include cases in which the colon bacillus or staphylococcus, separately or together, were involved. In cases of mixed infections mixed bacteriophages, polyvalent for colon bacillus and staphylococcus, were used.

There have been a number of reports of the successful use of bacteriophage in the treatment of infected wounds. McKinley⁷⁴ reported good results in the treatment of three staphylococcal wound infections but noted marked reactions even when the bacteriophage was applied in the form of a wet dressing. Rice⁷⁵ records excellent results in forty of forty-four wound infections, Dutton,⁵⁶ good results in forty cases. In these cases the bacteriophage was instilled into the wound or applied in the form of a wet dressing. Boyce, Lampert and McFetridge⁶⁵ treated forty-six wound cases with only two failures. Schultz⁵³ reports that eight of seventeen wound infections were "improved" by the use of bacteriophage. MacNeal⁷⁶ also reports favorable results in the treatment of *B. coli* and staphylococcal wound infections.

Similar good results have been reported in the treatment of abscesses and cellulitis by bacteriophage (Sauvé,⁷⁶ Rice⁵⁷ and Boyce, Lampert and McFetridge⁶⁵). Rice states that he has had the best results in abscesses that have not been opened. In these cases the bacteriophage is repeatedly injected into the abscess with a fine needle until liquefaction of the pus occurs. Incision and drainage are then followed by prompt healing. Many of the cases described are said to have been of long standing with no relief from therapeutic measures other than the bacteriophage.

76. Sauvé, L.: *A propos du bactériophage*, Bull. et mém. Soc. nat. de chir. 56: 348-354 (March 15) 1930.

Successful treatment of a number of cases of peritonitis and appendical abscesses by instillation of bacteriophage has been reported by Rice⁶⁷ and Rixford.⁷⁷ Ruddell, Sicks and Loomis⁷⁸ report the results of treatment of twenty-seven cases of ruptured appendix with local or general peritonitis. In these cases the bacteriophage preparation was left in the peritoneal cavity after operation. Three of the twenty-seven patients so treated died. The others convalesced at various rates, depending on the severity of the infection.

Other suppurative conditions treated by bacteriophage include infections of the nasopharynx (Théobalt and Moline,⁷⁹ McKinley⁷⁴ and Rice⁵⁷), lung abscesses (McKinley⁷⁴), puerperal sepsis (Rice,⁵⁷ Ruddell, Sicks and Loomis,⁷⁸ MacNeal^{70b}), and hordeolum and other eye infections (Town and Frisbee⁸⁰ and Larkum⁸⁰).

Several other investigators besides those already cited have treated large series of cases of suppurative conditions. Dalsace, Hauduroy and Camus⁸¹ treated 154 cases of staphylococcal infection with local injection and wet dressings of bacteriophage. They observed an average of 76 per cent of permanent cures in about four to five days. Chronic infections were the least affected. Bazy⁸² treated all sorts of surgical infections with bacteriophage. He observed good results in staphylococcal infections only and believes that the action may be due to the bacterial products contained in the lytic filtrates. Sauvé⁷⁶ reported that in 200 cases of staphylococcal and *B. coli* infections treated by bacteriophage there were only eight failures, cures being obtained in from five to ten days. In many cases cures were obtained in less than three days in conditions that usually required much longer to heal. This author also believes that substances in the filtrates other than the bacteriophage may play a part in the therapeutic effect. Christ⁸³ also reports cures in cases of staphylococcal and *B. coli* infections treated by the usual methods of surgical intervention as well as by bacteriophage. In some instances striking cures occurred in cases in which previous surgical therapy had failed.

It is impossible to read these many reports of the successful bacteriophage treatment of suppurative conditions without feeling that a great many of the authors are extremely uncritical. It is difficult to believe that success in from 95 to 99 per cent of cases has been due to a therapeutic agent that has proved so disappointing in the more critically conducted laboratory experiments. A consideration of many of the detailed case reports of what are stated by the investigators to be dramatic cures reveals that the process of recovery has not run an unusually swift course. Many of the conditions treated are self limiting, and, in those which are not, the usual methods of surgical intervention have been practiced. The fact that the patient recovered has,

therefore, little significance. The speed of recovery as compared with other similar conditions not treated by bacteriophage may have some significance, but it is well known that many suppurative conditions may show prompt improvement in from twenty-four to forty-eight hours, especially after drainage has been instituted. The prevention of recurrence in such conditions as furunculosis and the healing of chronic suppurative conditions of long standing under bacteriophage therapy are perhaps the most convincing effects observed. These effects could well be due to the action of bacteriophage filtrates as vaccines.

A number of the investigators cited have tested their bacteriophages for potency against the infecting organisms from each case. When resistant forms were involved, the therapy was generally found to be without effect. Apparently some investigators have used stock or commercial preparations and reported good results when they were not certain that the bacteriophages used were active. For example, Boyce and his associates,⁸⁵ and Ruddell and his collaborators,⁷⁸ used bacteriophage preparations supplied by a commercial firm. They reported good or dramatic results in a considerable series of infections including peritonitis, furunculosis, abscesses and wounds, as already described. However, Straub and Applebaum⁸⁴ found that samples of bacteriophage preparations from the same company in the same year contained preservatives (which may destroy bacteriophage) and that the staphylococcus preparation contained a weak lytic agent, but there was no detectable lytic activity in the streptococcus or streptococcus-colon bacillus bacteriophage preparations.

Of the various suppurative conditions treated by bacteriophage, the results with furunculosis and staphylococcal abscesses seem most convincing. Acne and other pyodermias and osteomyelitis have apparently not responded very well. The reports concerning the septicemias and peritonitis are not very convincing, since there seems to have been little change in the mortality in these diseases as a result of bacteriophage therapy. Too few cases of staphylococcal meningitis treated by bacteriophage have been reported to warrant any conclusions. The use of the bacteriophage in infected wounds and other suppurative conditions appears, in our opinion, to require a more critical investigation before the therapeutic value of the agent in these cases may be claimed. Staphylococcal infections in general appear to have responded the best to bacteriophage therapy, *B. coli* infections to a less extent, and streptococcal infections very little or not at all.

Bacteriophage Therapy in Infectious of the Urinary Tract.—In general the accounts of bacteriophage therapy in urinary infections are not as enthusiastic as those of the treatment of some of the suppurative conditions already described. In the majority of cases *B. coli* was the infecting organism, sometimes mixed with staphylococcus and other bacteria.

From a consideration of the various papers it is evident that only certain cases of urinary infection are suitable for treatment with bacteriophage. Bacteriophage resistant organisms occur very frequently. Larkum⁸⁵ found that the urines of only 40 per cent

Bacteriophages in the bladder, *Biol. Absts.* **1**: 316, 1927.

of the patients examined by him contained susceptible organisms, and 36 per cent contained bacteriophage. Caldwell⁸⁶ made a study of 112 infected urines. Of these, twelve contained gram-positive spore bearing bacilli, and seventeen contained organisms of the *B. pyocyaneus* group. Of 100 urinary cultures of non-spore forming organisms, 74 per cent were lysed with bacteriophage from sewage filtrates and 7 per cent were not lysed. Twenty-six of these 100 urines contained native bacteriophage in association with every cultural group of organisms and cultures in every state of dissociation and all degrees of sensitiveness to lysis. Apparently contact of organisms and bacteriophage in the urinary tract did not necessarily produce forms resistant to lysis by other races of bacteriophage derived from sewage.

MacNeal⁷¹ and Cowie⁸⁷ have emphasized the importance of bringing the reaction of the urine near to p_H 7.0, by administering sodium citrate, before bacteriophage therapy is attempted. The acid reaction of many urines is sufficient in itself to inhibit the lysis of bacteria by bacteriophage.

Bacteriophage therapy has generally been found useless in pyelitis or cystitis secondary to some other disease of the urinary tract. Thus in abscesses of the kidney, obstruction, renal calculus, hydronephrosis, and renal tuberculosis, other measures are more effective, as stated by Hinman⁸⁸ and Ravina.⁸⁹ MacNeal, Frisbee and Applebaum⁹⁰ have recommended the intravenous use of bacteriophage in genito-urinary infections in which the lymph spaces or renal cortex are involved. They believe that successful bacteriophage therapy in urinary infections proceeds from above downward.

The methods of treatment of urinary infections with bacteriophage are quite varied. Probably the best results have been obtained by combined subcutaneous injections and irrigations of the bladder and renal pelvis with bacteriophage, as described by MacNeal.⁷¹ Intramuscular and oral administrations have also been used.

Dalsace,⁹⁰ using the oral, intramuscular and subcutaneous routes, cured six out of nine cases of staphylococcal urinary infection and obtained cures in two and improvement in eight out of twelve cases of *B. coli* infection, in which the organisms were sensitive to lysis in vitro. In two cases of staphylococcus and five cases of *B. coli* infection the organisms were resistant, and treatment failed. Munter and Boenheim⁹¹ treated thirteen cases of cystitis in infants and children by intramuscular injection of *B. coli* bacteriophage, observed a marked reaction in three cases and obtained no influence on the course in nine out of the thirteen cases. In several cases the organisms were resistant to lysis. Zdansky⁹² treated twenty cases of cystitis by introducing bacteriophage into the washed bladders. Six cases were cured. Three of these had not been treated exclusively by bacteriophage, and these three had long

resisted other measures. Cowie⁸⁷ treated eleven cases by subcutaneous injections. Six acute cases were cured bacteriologically in from three to five days and discharged with sterile urine at six, seven, twenty-six and seventy days. Five of these had previously been given urinary antiseptics. Four chronic cases were temporarily relieved, showing sterile urines, but later presented recurrences. In one case there was no effect in the first treatment but the urine became sterile and remained so for seven days after a second course of treatment. All the chronic cases had previously received other forms of treatment.

Frisch⁹³ and Voss⁹⁴ reported good results in the bacteriophage treatment of chronic cases of urinary infection. Christiansen,⁹⁵ however, records only fair results in the treatment of chronic pyelitis with bacteriophage. He states that better results might be obtained if due regard were paid to the presence of resistant forms and the reaction of the urine.

Krueger, Faber and Schultz⁹⁶ report a series of eighty-nine carefully studied cases of urinary infection in children. The causative organism was identified in each case and tested for lysis by the bacteriophage on hand. Only cases presenting bacteriophage sensitive organisms were treated. Autogenous lytic filtrates were used in the treatment of about half of the cases. When only slight lysis occurred the activity of the bacteriophage was increased by serial passage through several cultures of the infecting organism. Tests for naturally occurring bacteriophage in the urines were made with susceptible cultures of *B. coli*, Shiga dysentery bacillus, and staphylococcus. Of twelve acute cases, only one was caused by a resistant colon bacillus, whereas among seventy-seven chronic cases forty-two were infected with resistant organisms. Treatment consisted of subcutaneous injections and instillations into the bladder. Of sixteen chronic cases treated by pooled bacteriophage, three cases showed prompt recovery, and eleven gradual recovery, and two failed to respond. Among nineteen chronic cases treated with autogenous preparations of bacteriophage there were one prompt recovery, fourteen gradual recoveries, and four failures. In twenty-five patients the gradual recovery was not clearly attributed to the bacteriophage. These authors administered alkalinizing drugs in eight cases of acute urinary infection. Five patients reacted unfavorably with no appearance of bacteriophage, three recovered rapidly and the urine of each of these three patients contained a native bacteriophage that lysed completely the causative organism originally isolated. This observation indicates that alkalization of the urine may facilitate the natural occurrence of bacteriophage. Six cases of chronic pyelocystitis were treated with purified bacteriophage containing a minimum of bacterial protein. In none of these cases was any effect observed with the purified bacteriophage preparations, but all six of these cases later responded to treatment with unpurified bacteriophage. These observations of Krueger, Faber and Schultz leave considerable doubt as to how much if any value may be attributable to the bacteriophage itself as a therapeutic agent in urinary infections.

Schultz⁹⁷ presents the following summary of the clinical results reported to him by physicians to whom bacteriophage had been supplied:

Of 151 cases of chronic *B. coli* pyelitis or cystitis, seventy-two were cured or improved, seventy-nine unchanged. In seventeen of the cases reported improved there were recurrences. In forty-two cases there seemed to be no question as to the immediate response to the treatment, and all these cases with two or three exceptions seem to have been free of anatomic disturbance. On the other hand, among the seventy-nine cases which failed to respond, associated pathologic conditions were present in a considerable number. Larger quantities of bacteriophage up to 50 cc. instilled into the urinary tract seemed to produce better results. Thirty-five of the forty acute cases responded promptly, twenty-seven of these becoming clear within forty-eight hours. In cases of cystitis and pyelitis caused by organisms other than *B. coli*, two of four cases of staphylococcal infection, and two of *Streptococcus faecalis* infection responded promptly. No results were obtained in cases of hydronephrosis and pyonephrosis. In prostatitis and seminovesiculitis caused by staphylococcus, two of seven cases were improved by bacteriophage treatment. Two cases of *B. coli* prostatitis treated by instillations into the bladder responded within forty-eight hours.

Cline⁹⁸ has also reported the successful treatment of twelve cases among fourteen of pyelitis in children by subcutaneous injection of *B. coli* bacteriophage. The author points out that most cases of pyuria in children respond well to careful medical management, but he also hopes that the use of bacteriophage may reduce the number of cases which ultimately require surgical intervention.

The mechanism of the therapeutic action of bacteriophage in certain cases of urinary infection is as little understood as it is in other infections. Caldwell⁹⁹ found that bacteriophage administered by subcutaneous injection and instillation into the bladder could be detected in infected urines but disappeared when the urine became sterile. In many cases there was a simultaneous occurrence of bacteria and bacteriophage and in some cases the bacteriophage persisted for months after the treatment was discontinued. Larkum⁸⁰ found that artificial introduction of bacteriophage into the body resulted in the transitory presence of the lytic agent in the urine, but that this usually disappeared in twenty-four hours. These observations of Caldwell and Larkum indicate that bacteriophage persists in the urine only when strains of bacteria susceptible to or capable of carrying the bacteriophage without lysis are present. Under ordinary conditions the constant dilution of the bladder contents would tend to wash out the bacteriophage in a short time, as pointed out by Zdansky.⁹²

The inhibitory action of colloidal substances in the urine and the production of resistant forms of bacteria seem to present the real problems of bacteriophage therapy in uncomplicated urinary infections. Larkum is of the opinion that bacteriophagy can occur in the bladder but that the process is probably not identical with that in the test tube. Caldwell found that many of the bacteria resistant to one race of bacteriophage could be lysed by bacteriophage from another source.

The possible rôle of immunization in the therapy is also noted by Ravina,⁸⁹ who found that stock vaccines or autogenous vaccines gave good results in urinary infections.

It must also be noted that the uncomplicated chronic and acute cases which respond best to bacteriophage therapy are often very readily cured by other measures, whereas many of the cases that do not respond to this therapy may often be cured by suitable surgical or medical treatment. Recurrences of infection after bacteriophage therapy are apparently very frequent.

Pelouze and Schofield¹⁰⁰ stated that they produced a bacteriophage active against the gonococcus. They observed that water extracts of ten-day old cultures of the organisms on hydrocele fluid agar contain, after filtration through a Berkefeld filter, an agent that kills suspensions of the gonococcus in hydrocele fluid in from five to twenty-four hours. The active agent is termed "gonophage." Pelouze and Schofield state that the "gonophage" is transmissible in series by subculturing from organisms that have been subjected to the action of the filtrates for thirty minutes but have not been killed. Addition of unfiltered suspensions of these organisms to suspensions of normal gonococcus kills the latter in twenty-four hours. The "gonophage" is said to be strictly species specific and the gonococcus is not affected by *B. coli* or staphylococcus bacteriophages made in the same way as the "gonophage." The "gonophage" is active in dilutions of 1:1,000. The gonococci in the suspensions used were not actively growing, and Pelouze and Schofield were unable to demonstrate any distinct clearing of the suspensions or any plaque formation in gonococcus colonies on agar. No attempts to transmit the "gonophage" in series by filtrates of cultures acted on by it, as may be done with true bacteriophages, are reported. Forty patients with acute gonorrhea were treated by subcutaneous injection of the "gonophage." Although some results that might be considered favorable were obtained, on the whole the course of the disease was not shortened or changed. Instillation of the "gonophage" into the urethra resulted in a purulent response and edema, which Pelouze and Schofield believe to be due to a gonotoxin contained in the filtrates.

Schmidt-Labaume and Fonrobert¹⁰¹ and Balozet and Lepinay¹⁰² have also observed the occurrence of a growth inhibiting substance in filtrates of gonococcus cultures and gonorrheal discharges, but this substance was not transmissible in series. These investigators were unable to demonstrate the production of gonococcus bacteriophage either in test tube or animal experiments.

There is no convincing evidence that a bacteriophage against the gonococcus has yet been discovered.

Schultz⁹⁷ has suggested the use of bacteriophage against the secondary invaders, such as staphylococcus in gonorrhea, but so far the number of cases treated in this way has not been large enough to warrant any conclusions.

Bacteriophage in the Treatment of Enteric Diseases.—Bacteriophage has been used quite extensively in the treatment of typhoid and paratyphoid fever, the bacillary dysenteries, and cholera. In the majority of cases

the lytic agent has been administered by mouth. Apparently few of the investigators using this method of treatment have taken the trouble to investigate the possible destructive action of the acid gastric juice on the bacteriophage and the inhibitory action of various secretions of the gastro-intestinal tract. Riding²⁵ reports that dysentery bacteriophage was not destroyed by hydrochloric acid at pH 3, but he found that intestinal mucus inhibited its action. Arnold and Weiss¹⁰³ showed that bacteriophage was not destroyed by trypsin, although Wollman¹⁰⁴ showed that certain races of Shiga bacteriophage were inhibited by trypsin, while other Shiga bacteriophages and the *B. coli* bacteriophages were not. As previously stated, bile is inhibitory to the lytic action of bacteriophage. From the evidence that can be found, it appears that the various substances in the gastro-intestinal tract may or may not have inhibiting actions, depending on the race of bacteriophage used and the physiologic state of the patient at the time of treatment. When the bacteriophage is given by subcutaneous or intravenous injection, its action on bacteria in the wall and lumen of the intestine might be less subject to inhibition, provided it is actually excreted into the intestine; but this point has not yet been adequately proved.

Although bacteriophage is readily recovered from the feces of man and animals, there is little evidence as to what extent lysis of bacteria occurs in the intestinal canal. d'Herelle is of the opinion that the recovery from certain diseases, such as typhoid, dysentery and cholera, is due to the development of bacteriophage, which then destroys the causative organisms. He states that he proved this contention by the frequent demonstration of bacteriophage in the stools of convalescents. It has been shown by a number of investigators, however, that bacteriophage may occur in the intestine of patients dead of enteric diseases, and that in convalescents no bacteriophage may be demonstrable. Examples of this have been furnished by Hauduroy,¹⁰⁵ Lisbonne and Boulet,¹⁰⁶ Taylor, Greval and Thant,¹⁰⁷ and Burnet, McKie and Wood.¹⁰⁸

Bacteriophage in the Treatment of Typhoid and Paratyphoid Fever.—Beckerich and Hauduroy¹⁰⁹ were among the first to use bacteriophage in the treatment of these diseases. They administered bacteriophage by mouth and subcutaneous injection in five cases of typhoid and in two of paratyphoid, with two failures and several questionable responses. Smith¹¹⁰ treated seven cases of typhoid by bacteriophage and obtained an improvement in symptoms in five cases that showed negative blood cultures. In the two cases with positive blood cultures no response was observed. Violle and Roure¹¹¹ observed marked reactions consisting of rise in temperature and chills after oral administration of bacteriophage to patients with typhoid. In some cases

bacteriophage was detected in the blood twenty-four hours after treatment. Only questionable responses were obtained. Cowie⁸⁷ treated several cases of typhoid with typhoid bacteriophage isolated from the stools of convalescent scarlet fever patients but obtained no beneficial results. He found that the bacteriophages isolated from scarlet fever patients were more active against the typhoid bacillus than those isolated from typhoid patients. Rutschko and Melnik¹¹² treated seventeen cases of typhoid by subcutaneous bacteriophage injections and fifty-two by oral administration of bacteriophage. In most cases the treatment was given in the second or third week of the disease. Reactions indicated by diarrhea, reappearance of rose spots and increased pyrexia followed the administration of the bacteriophage. This was generally followed by a fall in temperature and relief of symptoms. These effects were noted in about 50 per cent of the cases. The cases least affected were those treated by mouth. In the sixty-nine cases treated by bacteriophage there were four deaths, a mortality rate of 5.8 per cent. The mortality rate in cases not treated by bacteriophage was from 7.5 to 8.5 per cent. Gernez and Breton¹¹³ treated eight cases of typhoid and paratyphoid fever by intravenous injection of bacteriophage freed from all but traces of protein by electrophoresis. This preparation gave no reactions, but a fall in temperature and a rapid disappearance of symptoms were noted. One case was cured in five days. Dutton⁵⁰ obtained marked improvement in nine cases of typhoid and no effect in nine others. Strains from several of the improved cases were found to be resistant to the action of the bacteriophage used.

This brief summary of some of the literature on the treatment of typhoid with bacteriophage indicates that this agent has, apparently, no striking effect on the course of the disease except perhaps on the production of reactions followed by temporary relief. Especially is this the case in patients treated by injection of the lytic agent.

Bacteriophage in the Treatment of Bacillary Dysentery.—Like the accounts of the bacteriophage treatment of typhoid, the reports of the therapeutic value of bacteriophage in dysentery are conflicting and for the most part inconclusive. Spence and McKinley¹¹⁴ treated twenty proved cases of dysentery, nine due to Shiga bacillus and eleven to the Flexner type, with a bacteriophage lytic for the organisms and administered in doses of 10 cc. by mouth three times a day. At the same time twelve cases were treated by the usual methods. The average time, after onset of the disease, at which treatment was begun was 3.1 days. In the bacteriophage treated cases the average time of recovery from the beginning of treatment was 5.8 days and the mortality was 10 per cent. In the twelve patients not receiving bacteriophage the recovery time was 12.8 days and the mortality 40 per cent. Compton¹¹⁵ summarized the results reported by physicians who used a polyvalent bacteriophage in the treatment of sixty-six cases of bacillary dysentery. In thirty-five cases there was a

reduction of the number of stools to two or three a day and marked general improvement by the second day. In sixteen cases there was some reduction in the number of stools and slight or no general improvement. In fifteen cases there was no effect by the fourth day after treatment, or death occurred. The treatment was seldom successful in children under 1 year of age. Failures varied from 22 to 46 per cent in the age group 1 to 10 years. No complete failures in patients over 10 years of age were reported. Early treatment before the third day gave only 10 per cent of failures, while in cases treated after the fourth day there were from 35 to 50 per cent of failures. Taylor, Greval and Thant¹⁰⁷ observed the effects of oral administration of bacteriophage of high activity to twenty-six cases of proved bacillary dysentery and compared the results obtained with twenty control cases, the stools being tested daily for bacteriophage. Despite the presence of bacteriophage of higher activity in the stools of treated patients, as compared with the controls, no material difference was observed in the progress of the patients in regard to either duration or mortality. A detailed examination of cases showed no relationship between the incidence of bacteriophage, either naturally developed or artificially administered, and the progress of the case. Riding²⁵ treated a series of forty proved cases of dysentery with a highly active bacteriophage supplied by d'Herelle. Eight cases served as controls. The bacteriophage was administered by mouth. No dramatic results of the treatment were demonstrated. Riding could not detect bacteriophage in the stools of normal individuals who had received 4 cc. by mouth. London¹¹⁶ reports treating orally with bacteriophage a series of 141 cases of dysentery which were not diagnosed bacteriologically. Seventy-two control cases were treated with emetine and saline. In the group receiving bacteriophage the mortality was 8.5 per cent and the average duration twenty-one days. In the group receiving emetine and saline the mortality was 12.5 per cent and the average duration eighteen days. The lack of proper bacteriologic control to differentiate amebic from bacillary dysentery in this series of cases makes the results less significant than they might have been. Kessel and Rose¹¹⁷ treated alternate cases with bacteriophage by mouth in a series of sixty-eight cases of Flexner type dysentery, mostly in infants. Cases caused by bacteriophage resistant organisms were not included in the first series of twenty-two cases in which isolation of the organism and tests for in vitro bacteriophages were done before bacteriophage was given an average of four days after admission. In the second series of forty-four cases stock bacteriophage was administered immediately after hospitalization. All patients received the same routine systemic treatment. No difference in the course of the disease or the mortality (four deaths in the treated and three in the untreated group) could be detected in the thirty-four treated cases as compared with the thirty-two untreated cases. Administration of bacteriophage by enema was also without effect. These authors also quote a report by Asheshov, Taylor and Morison,¹¹⁸ who observed fifteen deaths in fifty-seven bacteriophage treated cases and fifty deaths in ninety-two untreated cases.

These results indicate that, despite the enthusiastic predictions of d'Herelle, the oral administration of bacteriophage in cases of bacillary dysentery has little effect. Injections of bacteriophage appear to have been tried only rarely in these diseases. Some of the work indicates that bacteriophage administered by mouth in cases of dysentery may at least occasionally be excreted in the feces, but it is doubtful whether any lysis of the causative organism in the intestine actually occurs. Despite these inconclusive results Charnock¹¹⁹ has recently stated in a review that the use of bacteriophage has met with greatest success in enteric diseases and that it is used as the sole treatment for bacillary dysentery in Brazil by Da Costa Cruz. (See also d'Herelle.⁴⁸)

Bacteriophage in the Treatment of Cholera.—A short review of several papers on this subject is included here because d'Herelle's¹²⁰ reported dramatic successes in the treatment of cholera are often cited by authors seeking to establish the therapeutic value of bacteriophage. d'Herelle, as a result of the study of cases of cholera in India, reported that mortality in bacteriophage treated cases was 8 per cent and in untreated cases 62 per cent. He claims to have stopped epidemics of cholera in certain localities by adding cholera bacteriophage to the drinking water. He also believes that the cholera bacteriophage is disseminated through the excreta of treated and convalescent patients, thus "propagating recovery."

More recently Morison¹²¹ has attempted to confirm these conceptions of d'Herelle. Two areas in India were selected, one of these was used as a control, and in the other bacteriophage was dispensed for the treatment of all cholera cases. In 1930 sixty-three cases were treated with bacteriophage. During the latter half of 1930 and all of 1931 there was no epidemic of cholera in the bacteriophage treated area, whereas in the control district there were four small epidemics in the same period of time. At the time the report was published the results were not conclusive but it has been reported in an unpublished communication that since 1930 there have been numerous cases of cholera in the control area and none in the area where bacteriophage was used.

Taylor, Greval, and Thant,¹⁰⁷ using a cholera bacteriophage of maximum activity, observed a mortality of 57 per cent in fourteen treated cases of cholera compared to a mortality of 53 per cent in a group of nineteen controls. Alternate cases were treated and stools were examined for the presence of cholera vibrio and bacteriophage. In the majority of cases that recovered no bacteriophage active for the causative organism was found in the stools. The authors conclude that recovery from cholera is independent of the action of bacteriophage and the therapeutic administration of bacteriophage is without effect. Souchard¹²² has also attempted to confirm the work of d'Herelle. This author used a bacteriophage supplied by d'Herelle, prepared it in the same way and increased its activity by serial passages through cholera vibrio cultures. Oral administration of 6 cc. in unselected cases was done just as d'Herelle had described. Despite all these precautions to imitate the methods used by d'Herelle, the mortality in a group of twenty-seven treated cases was 89 per cent, only

three recoveries being obtained. This mortality was identical with the prevailing mortality in untreated cases at the same time in the same locality. This author did observe, however, that in some cases, when administered early in the disease, the bacteriophage appeared to cause a temporary remission in symptoms and prolonged life, although the end result was the same as in untreated cases.

(To be continued)

Therapeutics

THE THERAPY OF THE COOK COUNTY HOSPITAL

EDITED BY BERNARD FANTUS, M.D.
CHICAGO

NOTE.—In their elaboration, these articles are submitted to the members of the attending staff of the Cook County Hospital by the director of therapeutics, Dr. Bernard Fantus. The views expressed by various members are incorporated in the final draft for publication. The series of articles will be continued from time to time in these columns.—ED.

THERAPY OF CHANCROID AND BUBO DIAGNOSIS

A few days after exposure there is a soft, flabby erosion and then an ulcer, which is inflammatory, painful and tender. It may be single or multiple and has an irregular, undermined border and an uneven base covered by a dirty purulent exudate. The streptobacillus of Ducrey can be found in the exudate.

Chancroid and its bubo must be differentiated from (1) syphilitic infection, (2) fusospirochetal balanitis, (3) granuloma inguinale, (4) lymphogranulomatosis inguinale, (5) herpes progenitalis and (6) epithelioma.

1. Every ulcer on the genitalia of a sexually active person should be considered a syphilitic chancre until proved otherwise and no treatment should be addressed to it until an absolute diagnosis has been made. In untreated cases, dark field examination for *Spirochaeta pallida* is positive in more than 90 per cent of syphilitic cases even on first examination. If the ulcer has received treatment, especially with mercury preparations, this should be removed, the sore cleansed and kept clean with physiologic solution of sodium chloride frequently applied and the dark field examination repeated for three successive days. Material removed by puncture of one of the regional glands may be used for the dark field examination if the lesion itself is contaminated by applications. If it still remains negative, exudative material from the lesion may be used for a Wassermann test or microscopic precipitation test such as the Kahn. Only after this has been found negative may more active local treatment be applied. A Wassermann "follow up" with weekly tests if possible for the first six weeks or at least a test on the fourth, eighth and twelfth week and the fourth month is essential in all dark field negative sores, if the all important early diagnosis of syphilis is to be made in all cases; for mixed infection is by no means rare.

2. Fusospirochetal (gangrenous) balanitis must also be ruled out. This is due to fusospirochetosis (q. v.) and is characterized usually by a single lesion with pus of a characteristically foul odor in which the fusiform bacillus and the spirochete are easily found on micro-

scopic examination after staining with dilute carbol-fuchsin. Its characteristic appearance is a very acutely inflammatory one. There is often a history of oral contact. The importance of the prompt recognition of this, though it is rare, will become evident when it is appreciated that local treatment by oxidizing agents (e. g., continuous drop by drop irrigation with Solution of Hydrogen Dioxide or saturated solution of Sodium Perborate) after a dorsal slit, if this is required by phimosis, together with Neosarsphenamine internally, may save extensive destruction or deformity of the penis on account of the fulminating nature of the inflammation and the often rapid extension of the disease. A blood count should be made before giving Neosarsphenamine to rule out agranulocytosis (q. v.).

3. Granuloma inguinale should be excluded by searching for Donovan bodies (inclusion bodies in the leukocytes). Even if these bodies are not found, unusual indolence and chronicity of the condition justify the prompt use of Antimony and Potassium Tartrate intravenously. Antimony thioglycollamide is also effective. In refractory cases, surgery should be resorted to.

4. Lymphogranulomatosis inguinale must also be considered. It starts with a papular lesion from pinhead to pea size or as a small erosion, which heals without a scar. A couple of weeks later the regional lymph glands on one or both sides enlarge and are firm. They become inflammatory and attach themselves to the overlying skin, which becomes livid in color and breaks down to form a sluggish, indolent, painless ulcer. There is sinus formation from the underlying glands to the surface. A Frei test is helpful in making a diagnosis. This is an intracutaneous test which utilizes an antigen made from the pus of a known positive case. A positive test is indicated by the local formation of a firm papule from forty-eight to seventy-two hours after inoculation. Treatment is by surgical extirpation before the formation of fistula. Other procedures have been advocated, such as graduated doses of the Frei antigen given intracutaneously.

5. Herpes progenitalis should be thought of in multiple, grouped, essentially vesicular lesions, resulting in shallow ulcers with crusts, preceded by itching or burning and having a tendency to recurrence. Nevertheless, in spite of even a characteristic appearance, its occurrence after coitus necessitates examination for exclusion of the more serious venereal ulcerations.

6. Epithelioma generally occurs after the fourth decade. It starts as a small papule or nodule, which grows slowly. It is hard, indurated, may break down to form a sluggish ulcer, heals partially with scar formation, and has a tendency to bleed. A biopsy is helpful in making the diagnosis.

CHANCROID

Prophylaxis.—Chancroids are not likely to appear on genitalia that are kept clean. The plentiful use of soap and hot water after coitus practically always suffices to prevent the infection.

Treatment.—The first stage of the treatment of chancroid aims at the destruction of the specific infection with the streptobacillus of Ducrey. As this bacillus cannot withstand temperatures over 115 to 120 F., heat should constitute an important item of the treatment. Cauterization is no longer practiced. It is not necessary and it seems to predispose to bubo. Keeping the patient at rest lessens the liability. Once a clean granulating surface has been secured, ulcer therapy (q. v.) should be resorted to.

1. **Cleansing:** Immersion of the penis in a jar filled with a 1:5,000 solution of Potassium Permanganate (prescription 1), as hot as can be borne, should be continued for fifteen minutes every two hours. If there is phimosis, irrigation by means of a soft rubber "ear syringe" with the hot Potassium Permanganate solution should be assiduously practiced in order to avoid, if possible, surgical methods that bring with them the danger of gangrenous phagedena.

2. **Dressing:** For the choice of dressings in the intervals between the soakings and irrigations, the following indications may be drawn:

(a) A dusting powder may be used for relatively small and readily accessible lesions. Application of Iodoform or, in those who object to its odor, of Thymol Iodide is admissible.

(b) Painting on a 5 per cent solution of Iodoform in ether or a paste made with 1 per cent solution of Phenol is better than the dry powder, which is liable to form a crust under which pus may accumulate. Care that no iodoform is spilled on the clothing or on the fingers may render its use less objectionable. It is well to protect the surrounding tissue with Boric Acid Ointment, to cover the sore with a pledget of gauze thinly spread with petrolatum, and to apply a condom.

(c) Moist dressings are indicated in cases presenting much swelling. A strip of gauze soaked in the permanganate solution is slipped under the foreskin, and compresses with Solution of Aluminum Subacetate, diluted 1 to 10 with water, are used in the intervals

PREScription 1.—Potassium Permanganate

R Potassium permanganate..... 2.00 Gm.
Distilled water..... 100.00 cc.
Mix. Label: 10 cc. per liter of water, as hot as can be borne, for immersion or irrigation in chancroid. For urethral irrigation, 5 cc. per liter.

between irrigations or immersions, until the swelling has subsided.

(d) In chancroid of the urethra, hot irrigation with Potassium Permanganate (1:10,000) solution (prescription 1) followed by injection of Iodoform (3 per cent in oil) or better perhaps by iodoform bougies (prescription 2) should be done three or four times daily immediately after urination.

3. **Destruction of the Lesion:** This is indicated in the graver phagedenic types (ulcus molle serpiginosum). In such cases it is particularly important to keep the undermined border clipped flat and thoroughly cauterized. Pyrogallol may be used in 10 per cent solution, increased up to full strength if required. The actual cautery may be employed, or fulguration. Ultraviolet ray therapy has been advocated here. Radium used to the point of pronounced reaction may succeed when everything else has failed.

4. **Surgery:** If frequent irrigation with hot Potassium Permanganate solution and the compresses, as advised, do not suffice to reduce phimosis, a dorsal slit under Ethyl Chloride general anesthesia is required. Local infiltration anesthesia is not permissible, as it may cause dissemination of infection through the lymphatics. No sutures are to be used. The operation is followed by energetic treatment as described. Circumcision should not be performed until the wound is covered with clean granulations. If the frenulum is perforated, it is best to cut it through after bilateral ligation and then to apply iodoform paste.

5. **Systemic Treatment:** In cases that do not readily respond to this treatment, even though syphilis is not demonstrable, Neoarsphenamine (from 0.4 to 0.6 Gm.)

intravenously may stop the progress of the advancing lesion. If the case is particularly obstinate, suggesting the possibility of an element of granuloma inguinale in the cause, one should resort to Antimony and Potassium Tartrate, giving intravenously a 10 per cent solution, beginning with doses of 1 cc. and increasing each dose given every other day by 1 cc. until a satisfactory result is obtained or until 10 or 12 cc. is given at a dose or the patient's limit of tolerance has been reached, which may be indicated by dizziness, coughing, vomiting, diarrhea, or aching in the back and shoulders, and occasionally toxic deafness. If the patient does not tolerate the Antimony and Potassium Tartrate sufficiently well, antimony thioglycollamide should be administered.

BUBO

Prophylaxis.—Prompt resort to absolute rest in bed, when groin tenderness or slight enlargement of the

Divide into ten urethral bougies. Label: Insert one after each urination.

lymph glands appears, and energetic treatment of the chancroid (but not by caustics) would probably prevent bubo formation in nearly every case.

Treatment.—A. Prior to Fluctuation: 1. Roentgen irradiation, 140 kilovolts with 0.25 mm. of copper and 1 mm. of aluminum, 75 roentgens, favors more rapid evolution and is especially indicated in torpid cases.

2. Nonspecific proteotherapy, as by means of intramuscular injections of sterilized milk, from 3 to 4 cc., may be employed, followed in three days by 5 cc. and, if this is well tolerated, after a similar interval by 10 cc.

B. When Fluctuation Appears: 1. Hot compresses with boric acid solution may still secure resolution. If it does not, or when fluctuation is very marked, the following treatment is indicated:

2. Puncture evacuation and injection should be done. A small incision is made in the fluctuating area of the swelling, and the pus is evacuated with gentle expres-

sion, a voluminous sterile gauze compression bandage is applied, and the patient is kept in bed for twenty-four hours. The bandage having then been removed, the pus is squeezed out as completely as possible, and the cavity ballooned out with Mancière's solution (prescription 3), the nozzle of the syringe (without any needle) being forced into the cut up to the neck of the syringe, which is firmly pressed against the skin to prevent escape of the fluid, which is permitted to escape after perhaps a minute. A heavy compression bandage, the patient keeping his legs extended, is permitted to remain for forty-eight hours and another reapplied for twenty-four hours. If, after the third day, there is still pus rather than serous fluid coming from the wound, another injection of Mancière's fluid is indicated. It should not be repeated earlier.

3. Surgery by wide incision, curettement or removal of the glandular mass is probably never necessary or indicated.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY OF THE AMERICAN MEDICAL ASSOCIATION HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS.
H. A. CARTER, Secretary.

BURDICK Z-12 ZOALITE LAMP ACCEPTABLE

Manufacturer: The Burdick Corporation, Milton, Wis.

The heating element for this infra-red lamp, made of ceramic material, is a single bar, nonmetallic surface unit, of 600 watts capacity. The reflector is double walled. The inner reflector is of polished aluminum alloy; the diameter is 10 inches and is protected with a wire screen. The telescopic stand is adjustable from 36 to 72 inches with a flexible arc. The lamp is arranged with a swivel feature, so that it will swing around. The base is equipped with four rubber tired ball-bearing casters. The upright and reflector casing is lacquered. The base is finished in enamel. The gooseneck and inner upright are of polished nickel.

In a laboratory acceptable to the Council, it was found that when connected to a 110 volt circuit the current read 4.5 amperes. Within an area of 70 cm. in diameter, at a distance of 1 inch from the edge of the reflector, the energy distribution was surveyed. In a small area of 30 cm. diameter, directly in front of the reflector, the radiant energy was 52 per cent more than at the edges.

The Council, therefore, includes the Burdick Z-12 Zoalite Lamp in its list of accepted devices.

BURDICK RV-85 ZOALITE LAMP, PRESCRIPTION MODEL, ACCEPTABLE

Manufacturer: The Burdick Corporation, Milton, Wis.

This model is designed to meet the requirements of a physician who wishes to prescribe heat therapy in the home. The heating element, made of ceramic material, is a single bar, nonmetallic surface unit, rated at 220 watts. The reflector is 9 inches in diameter and is of polished aluminum. The telescopic stand is adjustable from 41 to 61 inches. The lamp may be adjusted by means of a flexible gooseneck and swivel joint. The finish of the upright and reflector is in gray lacquer and polished nickel. Model Z-70 is essentially the same as Model RV-85, except for the finish.

In a laboratory acceptable to the Council, it was found that on a 113 volt alternating current line the current read 1.95 amperes. The energy distribution appears satisfactory for home treatments.

The Council, therefore, includes the Burdick RV-85 Zoalite Lamp, Prescription Model, in its list of accepted devices.

BURDICK Z-75 ZOALITE LAMP ACCEPTABLE

Manufacturer: The Burdick Corporation, Milton, Wis.

This is a localizing lamp for specialist service. It may be supplied with a stand, model Z-76, or with a special clamp for attaching to any other floor stand. The capacity of this unit is 75 watts. On a test conducted by the Council, it was found that when connected to a 114 volt alternating current line the current drawn was 0.6 ampere. Most of the radiant energy is confined to a comparatively small cone, since it is designed for localized heat treatments.

The Council, therefore, includes the Burdick Z-75 Zoalite Lamp in its list of accepted devices.

BURDICK Z-30 ZOALITE LAMP ACCEPTABLE

Manufacturer: The Burdick Corporation, Milton, Wis.

The heating element of this infra-red lamp, made of ceramic material, is a single bar, nonmetallic surface unit, rated at 1,000 watts. The reflector is double walled. The inner reflector, made of polished aluminum alloy, has a diameter of 18 inches. It is protected with a wire screen. The stand is counterbalanced, ball bearing, with 30 inch vertical adjustment, swivel cross arms, with 35 inch extension, 10 inch adjustment, and a mobile base with large rubber tired casters. It is finished

with nickel trimmings. The stand and base are of black enamel. The unit operates on both alternating and direct current.

By a test conducted in a laboratory acceptable to the Council, it was found that with a potential of 111.5 volts the current was 6.2 amperes when the heating element was cold and 5.8 amperes after burning for an hour. At a distance of 1 meter the plane in air having a diameter of 70 cm. was surveyed for energy distribution. Within a space 30 cm. diameter directly below the edge of the reflector, the energy distribution was 38 per cent more than at the edges.

The Council, therefore, includes the Burdick Z-30 Zoalite in its list of accepted devices.

Committee on Foods

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION, AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION. RAYMOND HERTWIG, Secretary.

VARSIITY EXTRA PALE DRY GINGER ALE

Manufacturer.—The Hibbard Laboratories, Cleveland.

Description.—Ginger ale; a carbonated beverage prepared from water, sucrose, citric acid, extracts of ginger root, grape and apple, oils of lime and orange and caramel color.

Manufacture.—Ginger root extract is prepared by steeping macerated ginger root in boiling water. An equal volume of ethyl alcohol and infusorial earth is added to precipitate out gums and resins, and the extract solution is decanted and filtered. The citrus oils and fruit extracts are added to the clear filtrate. The other ingredients in definite proportions are added to the flavoring solution. The final mixture is filtered, filled into bottles, cooled, five volumes of carbon dioxide are introduced under 70 pounds pressure and the bottles are sealed. City water treated with ultraviolet light is used.

Analysis (submitted by manufacturer).—

	per cent
Moisture	92.6
Total solids	7.4
Ash	0.02
Fat (ether extract)	0.0
Protein (N \times 6.25)	0.4
Reducing sugars before inversion as invert sugar	2.7
Sucrose	4.6
Carbohydrates (by difference)	6.9
Titratable acidity as citric acid	0.06

Calories.—0.3 per gram; 9 per ounce.

Claims of Manufacturer.—Complies with the United States Department of Agriculture definition for ginger ale.

WARFIELD PREMIER BAKING CHOCOLATE

Manufacturer.—Warfield Chocolate Company, Chicago.

Description.—"Chocolate liquor" or chocolate.

Manufacture.—Selected cacao beans are cleaned of foreign material, roasted, and broken to permit separation of the shells and germs. The shell-, germ-free nibs are finely ground, forming a "chocolate liquor," which is poured into molds to solidify. The solidified cakes are packed in cartons.

Analysis (submitted by manufacturer).—

	per cent	Moisture and fat-free basis, per cent
Moisture	1.9	
Ash	3.1	6.6
Fat (ether extract)	50.9	
Protein (non-caffeine and non-theobromine N \times 6.25)	19.9	42.2
Sucrose	0.0	
Crude fiber	1.0	2.1
Carbohydrates other than crude fiber (by difference)	23.2	49.0
Theobromine	0.77	
Caffeine	0.24	

Calories.—6.3 per gram; 179 per ounce.

Claims of Manufacturer.—Conforms to the United States Department of Agriculture definition and standard.

SATURDAY, DECEMBER 15, 1934

OPHTHALMOLOGY AND THE DISPENSING OPTICIAN

The view that examination of the eyes by a dispensing optician or optometrist is inadequate and usually uneconomical has been often expressed. Recently Harman¹ in England has employed the statistical method in attempting to determine the truth or falsity of this opinion. A number of ophthalmic practitioners, working in different parts of England, who were accustomed to seeing patients through the National Ophthalmic Treatment Board, were asked to keep records of the patients examined by them. To enable the records to be compared, cards were issued to these physicians, outlining the classification to be followed and the manner of entering the returns.

The report is based on 10,085 such cases recorded by forty-seven ophthalmic practitioners. Sixty-four per cent of the 10,000 cases showed errors of refraction only. Twenty-nine per cent showed errors of refraction plus one or more "other eye conditions." Nearly 6 per cent showed no errors of refraction but did present one or more "other eye conditions," and 1 per cent showed no appreciable eye defects. Thus, omitting those patients with errors of refraction only and those having no appreciable eye defects, 35 per cent of the patients seen required attention in addition to or other than the provision of glasses.

A partial check on these observations is provided by a still larger group of patients. Certain factors of all the cases seen through the National Ophthalmic Treatment Board are recorded and filed. One of these factors shows how many patients are reported by the ophthalmic medical practitioners as not requiring glasses. From this source 68,044 patients who were seen by 821 physicians were analyzed. Slightly more than 6 per cent did not require glasses, as contrasted with 6.75 per cent in the other more detailed analysis.

Comparative figures on patients seen by dispensing opticians were difficult to obtain. Harman sought to

determine what proportion of cases seen by opticians were similarly reported and referred to ophthalmologists for further study. Judging from the statistical inquiry noted, adequate optician examination should result in the referring to medical men of about 35 per cent of all patients seen, as the opticians admit only the ability to prescribe glasses for difficulties of refraction. Eventually actual figures of referred cases during 1933 or 1933-1934 were supplied by certain approved societies representing several million insured persons. In these returns the percentage of cases referred by the sight-testing opticians to ophthalmic surgeons ranges from 1 to 4.6, with an average of 3. The comparison is striking. In the series of patients examined by ophthalmic surgeons, 29 per cent proved to be other than errors of refraction alone, and nearly 6 per cent had other eye conditions without errors of refraction, yet only 3 per cent of the patients seen by opticians were referred for further examination.

"The conclusion," Harman says, "is irresistible. The opticians did not recognize the defects present in the eyes of the patients seen by them, or if they did recognize them they did not report them for medical examination. The corollary is this. Patients who go to opticians to have their sight tested do not get what they ought to get. Such a finding is conclusive of the proposition that an examination by an optician is uneconomical, and conversely that approved societies or others who are responsible for advising patients to seek eye examination cannot in the interests of these persons do other than adopt the only economical method—that is, by securing examination by competent ophthalmic medical practitioners."

INFANT MORTALITY IN 1933

The statistical report¹ on infant mortality in 985 cities of the United States during 1933 contains several features of especial interest. The report includes infant mortality data for every city of 10,000 population and more, as the result of the inclusion for the first time of cities in Texas and South Dakota. Because of recent statistical research, the detailed tables in this year's report differ from the tables previously presented in that the annual rate for 1933 is given only for those cities in which there were more than 450 births. The reason for this change is that the rates for small cities have little significance, owing to the wide fluctuations in rate from year to year, which is explained by the small number of births on which they must be based.

The urban infant mortality rate for 1933 is 57.1. This figure is based on 983 cities in the continental United States and two cities in Hawaii. It is 0.3 point higher than the rate for 1932, which was based on 943 cities in the birth registration area. The slight increase,

1. Harman, N. B.: The Findings of Eye Examinations, Brit. M. J. 2: 181 (Oct. 6, supplement) 1934.

1. Brandeis, Olga, and Derryberry, M.: Statistical Report of Infant Mortality for 1933, American Child Health Association, July 1934.

in rate is due wholly to the relatively high rate in the cities of Texas. If the rate for 1933 is computed on the same 943 cities that are given in the 1932 report, the rate is 55.9, which represents the lowest urban rate ever recorded in the history of the country. It is therefore safe to conclude that there has been no real increase in the infant deaths.

Of the cities with a population of more than 250,000, Portland, Ore., had the lowest rate and Memphis, Tenn., the highest. Of those with a population between 100,000 and 250,000, Fort Wayne, Ind., had the lowest and El Paso, Texas, the highest rates. Of cities between 50,000 and 100,000, Berkeley, Calif., had the lowest rate and Charleston, W. Va., the highest. In appraising these rates, however, it must be borne in mind that they are crude and not corrected rates. They are based on the births and deaths reported as occurring in the city and not the place of residence. It is hoped that ultimately vital statistics will be corrected for residence. This has been done in fact for three states: Connecticut, New Jersey and New York. In seventy-three of the cities in these states, comparable crude and corrected rates were obtained. In only seven did the rates remain the same after correction. In forty-three cities the rate was increased and in twenty-three decreased.

The larger cities have rates somewhat lower on the average than the smaller cities. The lowest among the ten largest cities of the country was 44. This rate was reported for both St. Louis and Cleveland. Chicago, which had the lowest rate in 1932, and Philadelphia were tied with a rate of 49. Six of these large cities had a lower rate than in the preceding year, two were unchanged and in two there was a slight increase. In 1932 all rates in the ten largest cities were below 70 for the first time since publication of the reports, and in 1933 they were all below 65. The highest urban rates were found, in general, in the Southern and South-western states. These high rates were chiefly due to the high infant mortality among the large Negro population. Although there has been no general increase in the urban infant mortality rate for the country as a whole, there has been an increase in the Southern states as a group.

The report concludes that "failure to correct for residence may produce fictitiously high or low rates. But, even when this correction is made, one is not justified in using the infant mortality rate as a reliable measure solely of the quality of public health effort in a community. The infant mortality is a resultant of a number of causes, such as social and economic status, family customs characteristic of different race and nationality groups, climatic conditions, the amount of modern medical service, as well as the amount and quality of public health effort." For this reason care should be used in ascribing a change in the infant mortality rate to any one of these many possible influences.

THE EFFECT OF DIETS ON CALCIUM AND PHOSPHORUS METABOLISM IN DOGS

Much excellent research has been directed toward the elucidation of the effects of special diets and of vitamins on the calcium and phosphorus metabolism. Morgan and her collaborators¹ intended primarily to study pyorrhea, but it was felt that a comprehensive study should take account of the changes in bones, blood and excretions as well as of teeth and gingivae.

The experimental observations were made on young dogs taken at weaning at ages of from 5 to 7 weeks. The dogs were placed on artificial diets made up of isolated foodstuffs and were kept on these diets for periods varying up to ten months. They were kept indoors in small pens, with occasional brief periods of outdoor exercise. Clinical mouth examinations, blood examinations and roentgenograms were made once a month. The weights were recorded weekly. At the end of the observation periods, histologic and chemical examinations were made on some of the tissues. The diets used consisted principally of casein, agar and sucrose, with the addition of salt mixtures of varying calcium and phosphorus content made alkaline, neutral or acid by the addition of sodium carbonate or ammonium chloride. Butter fat supplied vitamin A to those animals not receiving cod liver oil. Dried brewery yeast was given as the source of vitamins B and G. Two types of salt mixture were used, each made respectively acid, neutral or basic. There were hence twelve diets supplied: 1. Normal salt diets (a) without vitamin D: acid, neutral, basic; (b) with vitamin D (in cod liver oil): acid, neutral, basic. 2. Low calcium diets (a) without vitamin D: acid, neutral, basic; (b) with vitamin D (in cod liver oil): acid, neutral, basic.

The alkali-fed dogs were usually larger at every age than comparable animals on the other diets. A definite superiority in growth rate was observed also in the animals given cod liver oil. The roentgenograms indicated nearly normal conditions of bones in the greater number of dogs given cod liver oil, and rickets of varying severity in those without vitamin D. The dogs on acid diets without vitamin D showed the most severe lesions, the alkaline dogs the next most severe; the neutral dogs were the most nearly normal of the group. Of the group given cod liver oil, those on an alkaline diet seemed to have the least normal bone development, possibly because of accelerated growth. The low calcium group showed the most severe lesions of all, except the one animal that was given cod liver oil from the beginning. The low calcium dogs without cod liver oil were found to have developed osteitis fibrosa; the other vitamin D-free dogs, osteoporosis or osteomalacia. The blood p_H and plasma carbon dioxide capacity of the alkaline and acid dogs reflected their

1. Morgan, Agnes F., with the cooperation of others: The Effect of Acid, Neutral and Basic Diets on the Calcium and Phosphorus Metabolism of Dogs, Univ. of California Publications in Physiology 8: 61 (No. 7) 1934.

alkaline and acid conditions, but less markedly than might have been expected. Hemoglobin determinations, for the most part above 14 Gm. per hundred cubic centimeters of blood, indicated little change in water content of the blood. No variations were found that could be ascribed definitely to reaction of diet, vitamin D, or stage of bone lesions. The organic phosphorus of the whole blood was lowest in the dogs on acid diets without cod liver oil and highest in the dogs on neutral diets both with and without cod liver oil. The cod liver oil caused a significant rise of inorganic phosphorus only in the acid group. Considerably lower phosphorus values were seen in the low calcium dogs than in the others, but the cod liver oil appeared more effective in raising the blood inorganic phosphorus.

Total serum calcium remained at normal levels in all the dogs on normal diet but was slightly lower in the acid dogs, both with and without vitamin D, than in any of the others. There was some lowering of these levels in most of the low calcium group. Diffusible or ultrafiltrable serum calcium showed little variation, remaining close to 50 per cent of total calcium, and had only a slight tendency toward higher values in the acid group. The product $[Ca] \times [P]$ in terms of milligrams per hundred cubic centimeters of serum or blood was lowest in the group fed acid diets without vitamin D and highest in the neutral group. On low calcium diets these values varied somewhat, but the number of dogs was too small to form a basis for drawing conclusions from the values found.

The largest storage of both calcium and phosphorus occurred on the alkaline and neutral diets both with and without vitamin D and the lowest on the acid diets without vitamin D. One litter of setter pups, which had low retentions of these elements even when given cod liver oil, is thought to have suffered from the fact that their mother was deprived of direct sunlight during the pregnancy that resulted in their birth. Another litter of the same parentage, the mother leading an outdoor life during pregnancy, exhibited considerably better storage with the exception of one animal. The cod liver oil exerted a favorable effect on storage of both calcium and phosphorus in both the acid and the alkaline diets, but this was more marked in the acid diet. No such effect was seen in the animals on the neutral diets. With normal salt diets the percentage of ash in the bones and teeth was lowered only in the dogs fed acid diets without cod liver oil but was low in all the dogs on the low calcium diets except when cod liver oil was given throughout the feeding period. The ash content of the lower jaws and lower molars was greater than that of the upper jaws and upper molars, and that of the tibias was greater than that of the femurs. The ash phosphorus of the alkaline and neutral dogs of the low calcium group was normal or high, but that of the acid dogs was low. An exception was seen in one dog, which received cod liver oil and which was apparently normal by all tests made.

Histologic study of the tissues of seventeen of the dogs indicated that the clinical picture of osteitis fibrosa was produced by a low calcium diet in the absence of vitamin D. There was an exception in one dog fed a neutral diet, which showed severe osteoporosis. All the dogs on normal diets without vitamin D showed osteoporosis, a condition that was much reduced in severity by the administration of cod liver oil. Typical clinical parodontosis was seen in the low calcium group without vitamin D and in all the alkalinized dogs on normal diets as well. Also a larger amount of damage to kidney tissue was seen in the alkaline than in the other groups.

It is concluded that parodontosis in varying degrees of severity as well as renal damage may result from the long continued use of alkaline diets either with or without vitamin D and normal calcium-phosphorus ratio and content. This work, combined with that of others, e. g., Mellanby,² provides a broad foundation for further research and attempts at clinical application.

Current Comment

PHYSICIAN BECOMES ASSISTANT CHIEF OF CHILDREN'S BUREAU

As announced elsewhere in this issue of *THE JOURNAL* (p. 1863), Dr. Martha M. Eliot has been made assistant chief of the United States Children's Bureau in charge of all matters relating to health. The appointment of a physician to this position is a recognition of the importance of having those medically trained in charge of government activities of a medical character. Dr. Eliot has been director of the Division of Maternal and Child Health in the bureau and associate clinical professor of pediatrics in the Yale University School of Medicine. Her career in clinical medicine includes work in the Peter Bent Brigham Hospital, St. Louis Children's Hospital and New Haven Hospital, as well as investigations on growth, nutrition and rickets. She is a member of the American Pediatric Society, chairman of the Committee on Child Health Relations of the American Academy of Pediatrics, and a Fellow of the American Medical Association. She brings to her work not only this medical background but also an extensive experience in medical social service and family welfare work.

AGITATION FOR IMMEDIATE ACTION ON HEALTH INSURANCE

A letter is apparently being circulated by the American Association for Labor Legislation asking those to whom it is addressed to send telegrams immediately to Secretary of Labor Frances Perkins and the President urging immediate action on the subject of health insurance. Apparently the propagandists are not content to await the report of the President's Committee on Economic Security, of its technical staff or of its

2. Mellanby, May: Medical Research Council, Special Reprint Series 153, 1930.

various advisory boards but desire, regardless of the economic situation of the country as a whole or of any other important factors that may be involved, to jam some sort of legislation through immediately. Physicians whose advice may be asked concerning this appeal on the part of the American Association for Labor Legislation may well inform their inquirers of the desirability of caution and consideration in the development of any new methods of medical practice. Haste and carelessness prompted by evangelistic methods for social legislation must inevitably lead to errors and result in harm to both the public and the medical profession. The experience of every foreign nation precipitated into a sickness insurance scheme is evidence of the unfortunate possibilities that are incurred in the precipitous adoption of revolutionary measures.

Association News

MEDICAL BROADCASTS

Columbia Broadcasting System

The American Medical Association broadcasts on a western network of the Columbia Broadcasting System each Thursday afternoon on the Educational Forum from 4:30 to 4:45, central standard time. The next three broadcasts will be as follows:

- December 20. Social Security, Morris Fishbein, M.D.
- December 27. Budgeting for Health, W. W. Bauer, M.D.
- January 3. Housing and Health, W. W. Bauer, M.D.

National Broadcasting Company

The American Medical Association broadcasts under the title "Your Health" on a Blue network of the National Broadcasting Company each Tuesday afternoon from 4 to 4:15, central standard time. The next broadcast will be delivered by Dr. W. W. Bauer. The title will be as follows:

- December 18. Fight Tuberculosis With Modern Weapons, W. W. Bauer, M.D.
- December 25. Holiday; no broadcast.
- January 1. Holiday; no broadcast.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

CALIFORNIA

Annual Registration Due January 1.—Every practitioner of medicine and surgery holding a license to practice in California is required by law to register annually, on or before January 1, with the secretary-treasurer of the board of medical examiners, and at that time to pay a fee of \$1. Failure to pay the required fee within sixty days after January 1 works a revocation of a license and thereafter a license may be reissued only after application and the payment of a \$10 penalty.

Medical Economics Survey.—The medical economics survey approved by the house of delegates of the California Medical Association at its last annual meeting has been started. A committee of five for the study of medical care was appointed, including Drs. William R. Molony and Harry H. Wilson, Los Angeles, Alson R. Kilgore, San Francisco, Robert A. Peers, Colfax, and Rodney A. Yoell, San Francisco. The plans call for a twofold study. One, on the health and economic status of the general public, is to be conducted by field workers. About 1 per cent of the families in twenty-five counties will be reached, it is expected. The other aspect of the study involves an analysis of the medical and dental professions and of the hospital and public health facilities of California, to be made from the data obtained from questionnaires that

have been mailed to every physician, dentist, hospital and clinic in the state. The field work has already been completed in two counties. Paul A. Dodd, Ph.D., assistant professor of economics, University of California at Los Angeles, is director of the survey.

Symposium on Heart Disease.—The third annual heart symposium of the Los Angeles County Heart Association was conducted, December 6-7. The program was presented by the following physicians:

- Edward Richmond Ware, Embolism as a Manifestation of Heart Disease.
- Willard J. Stone, Subacute Bacterial Endocarditis.
- Egerton L. Crispin, Cardiac Neurosis.
- John C. Ruddock, Drug Therapy in Heart Disease.
- William H. Leake, Treatment of Auricular Fibrillation.
- Arthur M. Hoffman, Thyroidectomy in the Treatment of Congestive Heart Failure and Angina Pectoris.
- R. Manning Clarke, Syphilitic and Rheumatic Heart Disease.
- Roy E. Thomas, The Surgical Risk in Heart Disease.
- Francis M. Pottenger, Monrovia, The Heart in Tuberculosis.
- Donald J. Frick, Abnormalities of the Myocardium.
- Harold H. Smith, Treatment of Acute Coronary Occlusion.
- John L. Maroon, Santa Ana, Treatment of Syphilitic Heart Disease.

A joint meeting of the heart association with the Los Angeles County Medical Association formed the program for the evening session, Thursday; speakers were Drs. Arthur S. Granger on "Importance of Early and Accurate Diagnosis in Heart Disease" and Eugene S. Kilgore, San Francisco, "Some of Our Less Clear Conceptions of Coronary Disease." On Friday morning there was a clinical pathologic conference, with discussion of cases and demonstration of specimens by Drs. Newton G. Evans, Edward M. Butt, Verne R. Mason, Daniel D. Comstock, Burrell O. Raulston and William C. Boeck.

COLORADO

Society News.—Speakers before the Medical Society of the City and County of Denver, November 20, were Drs. Claude E. Cooper and Wilford W. Barber on "Congenital Cyst of the Right Ethmoid in a Child 3 Years of Age," and Dr. Glen E. Cheley, "Hyperinsulinism Associated with Langerhans' Adenoma Treated Surgically." Speakers before the society, October 16, were Drs. William B. Yegge on "Early Diagnosis and Prevention of Lead Poisoning"; John M. Foster, "Tumor of the Chest Wall"; Emeric I. Dobos, "Fundamental Principles Underlying Treatment of Diabetes," and Joseph F. Prinzing, "The Anatomy Concerned in Inguinal Hernia."

CONNECTICUT

Annual Registration Due During January.—Every practitioner of medicine and surgery holding a license to practice in Connecticut is required by law to register during January with the state department of health and at that time to pay a fee of \$2. Licentiatees who have retired from active practice or who live out of the state must register annually but need not pay a fee. A practitioner failing to register is liable to a fine of not more than \$5.

Society News.—Dr. John M. Birnie, Springfield, Mass., addressed the Tolland County Medical Association, October 16, on "Surgery of Infancy and Childhood."—At the semiannual meeting of the Connecticut Public Health Association, November 7, in Hartford, Drs. Clarence I. Scamman, New York, and Charles C. Wilson, Hartford, discussed "Efficiency Lines of Public Health Work" and "Economy as It Pertains to Medical School Inspection," respectively.

FLORIDA

Personal.—The Volusia County Medical Society devoted a regular meeting in DeLand, recently, to honoring Dr. and Mrs. George A. Davis, DeLand, on their fiftieth wedding anniversary.

Annual Registration Due January 1.—Every practitioner of medicine and surgery holding a license to practice in Florida is required by law to register annually on or before January 1 with the secretary of the state board of health and at that time to pay a fee of \$1. A licentiate failing to register annually is liable to a fine of not more than \$50.

GEORGIA

University News.—The Woman's Auxiliary of Emory University Hospital, Atlanta, is sponsoring a series of lectures in the auditorium of the institution on Tuesday afternoons; Dr. Lewellyn H. Muse recently discussed infectious fevers peculiar to childhood.

Survey of Maternal Mortality.—The committee on the study of maternal mortality and infant deaths of the Medical Association of Georgia has begun a state wide survey. Questionnaires will be issued to physicians throughout the state to

obtain the statistical data necessary. Authorization to proceed with the survey was given at the annual meeting of the state association in May. Dr. Emmett D. Colvin, Atlanta, is chairman of the committee.

ILLINOIS

Society News.—At a meeting of the La Salle County Medical Society, November 22, Dr. Frank Smithies, Chicago, gave a paper on "Biliousness: What It Means Pathologically and Chemically; Its Differential Diagnosis and Treatment."—Dr. Oliver S. Ormsby, Chicago, discussed "Mycotic Infections" before the Peoria City Medical Society in Peoria, December 4.

Chicago

Fracture Night.—Dr. Frederic J. Cotton, Boston, will be the principal speaker at the meeting of the Chicago Medical Society, December 19, designated "fracture night." His subject will be "Fractures and Other Injuries of the Hip." Participating in the discussion will be Drs. Philip H. Kreuscher, William R. Cubbins, Kellogg Speed, Beveridge H. Moore, Paul B. Magnuson, Edwin M. Miller and Edwin W. Ryerson.

Society News.—Dr. Jack D. Kirshbaum, among others, addressed the Chicago Pathological Society, December 10, on "Sarcomas of the Diaphragm."—Speakers before the Chicago Gynecological Society, December 21, will be Drs. Philip H. Smith on "Hemorrhage in Late Pregnancy"; David S. Hillis, "Diagnosis and Treatment of Late Hemorrhages in Pregnancy," and William J. Dieckmann and Edwin F. Daily on "Rôle of Blood Transfusion in Treatment of Obstetric Hemorrhage."—Dr. Frederick J. Gaenslen, professor of orthopedic surgery, University of Wisconsin Medical School, Madison, addressed the Chicago Orthopedic Club, December 14, on "Fractures of the Neck of the Femur: Experimental and Clinical Studies."

INDIANA

Memorial Meeting.—The Indianapolis Medical Society held a memorial meeting, December 7, in honor of the late Drs. John W. Carmack and Arthur M. Mendenhall, professor of rhinology, otology and laryngology and professor of obstetrics, respectively, at the Indiana University School of Medicine. Both physicians were killed in an airplane accident, December 5. They were returning to Indianapolis from Detroit, where they had attended a meeting. Dr. Mendenhall's daughter Evelyn was also killed.

Society News.—Dr. Arthur N. Ferguson, Fort Wayne, discussed "A Study of the Relief of Symptoms Following Cholecystectomy" before the Northeastern Indiana Academy of Medicine in Kendallville, November 22.—At a meeting of the Montgomery County Medical Society in Crawfordsville, November 22, Dr. Gerald W. Gustafson, Indianapolis, discussed problems in obstetrics.—Dr. Louis H. Segar, Indianapolis, considered the modern treatment of pediatrics before the Randolph County Medical Society in Winchester, October 8. The society was addressed, November 12, by Dr. Frank C. Walker, Indianapolis, on "Aphorisms of Gynecology."—The Madison County Medical Society heard Dr. James F. Balch, Indianapolis, discuss urologic problems at its meeting in Anderson, November 19.—Speakers before the Knox County Medical Society in Vincennes, October 18, were Drs. August F. Knoefel and Frank E. Sayers, Terre Haute, on osteomyelitis and vitamin and calcium therapy, respectively.—The Greene County Medical Society was addressed in Linton, October 18, by Drs. Everett E. Padgett on surgical conditions of the gallbladder, and Paul K. Cullen, biliary disease; both are from Indianapolis.—Dr. Frederick A. Collier, Ann Arbor, discussed "Mortality Factors in Acute Appendicitis" before the Fort Wayne Medical Society, November 6.—Dr. Theodore C. Hempelmann, St. Louis, discussed encephalitis before the Muncie Academy of Medicine, October 30.

IOWA

Society News.—At a meeting of the Washington County Medical Society, Dr. Thomas F. Suchomel, Cedar Rapids, discussed "The Treatment of Hernia."—The Woodbury County Medical Society was addressed in Sioux City, October 23, by Dr. William F. Mengert, Iowa City, on "Uterine Malignancies."—Dr. Morris Fishbein, Chicago, addressed the Des Moines Academy of Medicine and Polk County Medical Society, November 28, on "Our Changing Times." Speakers at the meeting, December 11, were Drs. Lawrence E. Kelley on "Management of the Toxemias of Pregnancy"; Raymond Cohen and Joseph B. Priestley, "Undescended Testicles, with Special Reference to Medical and Surgical Treatment."—Dr. Ray Lyman Wilbur, Stanford University, Calif., will speak before

the Linn County Medical Society, Cedar Rapids, December 18, on "The Relation of the Doctor to Society." Dr. Jesse T. Grayston, Marion, will present a paper on pilonidal cyst.

LOUISIANA

Dr. Mason Gives Chaille Memorial Oration.—Dr. James M. Mason, Birmingham, gave the ninth Stanford E. Chaille Memorial Oration at the meeting of the Orleans Parish Medical Society, December 5, in New Orleans. The title of the address was "Stanford Emerson Chaille as a Student Viewed Him."

Annual Renewal Due January 1.—Every practitioner of medicine and surgery holding a certificate to practice in Louisiana is required by law to have his certificate renewed annually, on or before January 1, by the secretary-treasurer of the state board of medical examiners, and at that time to pay a fee of \$2. The board may by unanimous vote revoke any certificate not renewed.

MAINE

Society News.—A symposium on dementia praecox was presented before the Kennebec County Medical Association in Augusta, October 25, by Drs. Joseph C. Rheingold, Israel Newman, Harry Elkins, Frederick R. Carter, Matthias Marquardt and Forrest C. Tyson.—The principal speaker before a joint meeting of the Penobscot-Hancock County medical societies recently was Dr. Forrest B. Ames, Bangor; his subject was "X-Ray and Its Relation to Medicine."—Speakers before the Washington County Medical Society, October 24, in East Machias, were Drs. Edwin W. Gehring, Portland, on collection agencies; Herbert S. Everett, St. Stephens, N. B., the Schilling differential blood count and its clinical significance, and John F. Hanson, Machias, coronary thrombosis.

MARYLAND

Personal.—Dr. William K. Skilling has been given a permanent appointment as director of the bureau of child hygiene of the Baltimore Health Department, effective October 1; the bureau was formerly known as the bureau of child welfare. Dr. Skilling has been with the health department since 1924.—Dr. Warfield T. Longcope, professor of medicine, Johns Hopkins University School of Medicine, Baltimore, received the honorary degree of doctor of laws recently from St. Johns College, Annapolis.

Farewell Dinner to Dr. Wilmer.—A farewell dinner was given to Dr. William H. Wilmer, November 19, by the boards of trustees of Johns Hopkins University and Hospital in Baltimore. Dr. Wilmer, who was officially retired as director of the Wilmer Institute of Ophthalmology in July, plans to return to Washington, D. C., where he practiced medicine from 1889 to 1925. He was professor of ophthalmology at Georgetown University School of Medicine from 1906 to 1925. In attendance at the dinner were Daniel Willard, LL.D., president of the board of trustees of the university; Mayor Jackson; Herbert L. Satterlee of the board of the Wilmer Foundation, and Mrs. Henry Breckenridge, originator of the foundation. Newton D. Baker, Cleveland, former Secretary of War, was toastmaster, and speakers included Drs. George E. de Schweinitz, emeritus professor of ophthalmology, University of Pennsylvania School of Medicine, Philadelphia, and William H. Howell, director emeritus of the School of Hygiene and Public Health of the university. The dinner was held in the hall of the Welch Medical Library.

MASSACHUSETTS

Dr. Gallie to Give Shattuck Lecture.—Dr. William E. Gallie, professor of surgery, University of Toronto Faculty of Medicine, will deliver the 1935 Shattuck Lecture of the Massachusetts Medical Society.

Dr. Rowe Dies.—Allan W. Rowe, Ph.D., since 1908 professor of chemistry, Boston University School of Medicine, and director of research at Evans Memorial Hospital since 1921, died, December 6, aged 55. Dr. Rowe graduated from the Massachusetts Institute of Technology in 1901 and received his degree of doctor of philosophy from the University of Göttingen, Germany. A member of many scientific societies, Dr. Rowe has contributed much to the literature on endocrinology and allergy. He was an honorary fellow of the Suffolk County Medical Society.

Research Expedition Returns.—The Harvard-African Expedition, which has been carrying on medical and biologic investigations on onchocerciasis in the Belgian Congo, has returned to this country. The expedition, which left last April under the direction of Dr. Richard P. Strong, was sponsored by the department of tropical medicine, Harvard Medical

School, Boston. Research on the material brought back from the expedition will be completed in the laboratories of the department by Dr. Strong and Jack H. Sandground, Sc.D. It was stated that in some of the villages in the Congo, about 95 per cent of the natives were infected with various degrees of onchocerciasis, many of them totally blind as a result.

Dr. Edsall Retires as Dean of Harvard.—Dr. David Linn Edsall will retire as dean of the faculty of medicine and dentistry of the medical school and of the school of public health of Harvard University, Sept. 1, 1935, and become dean emeritus. Dr. Edsall, who is 65 years of age, has been dean of the medical school since 1918. In 1893 Dr. Edsall graduated in medicine at the University of Pennsylvania, where from 1907 to 1910 he was professor of therapeutics and pharmacology, and from 1910 to 1911 professor of medicine. The following year he spent as professor of preventive medicine at Washington University, St. Louis. In 1912 he was appointed Jackson professor of clinical medicine at Harvard, becoming dean of the medical school and of the faculty of medicine in 1918. He has been dean of the school of public health since 1922 and of the faculty of dentistry since 1924.

MINNESOTA

Annual Registration Due During January.—Every practitioner of medicine and surgery holding a license to practice in Minnesota is required by law to register annually during January with the secretary of the board of medical examiners and at that time to pay a fee of \$2. A licentiate who practices without renewing his license is guilty of a misdemeanor and is liable to prosecution.

Symposium on Fractures.—The Minneapolis Surgical Society held its annual symposium on fractures, December 11, in the auditorium of the Hennepin County Medical Society. The following program was presented:

- Dr. Nels Harvey Nelson, Fracture Disability Estimation.
- Dr. Edward A. Regnier, Fracture of the Neck of the Femur.
- Dr. Roscoe C. Webb, Fracture of the Upper End of the Tibia Involving the Knee Joint.
- Dr. George R. Dunn, Fracture of the Os Calcis.
- Dr. Robert G. Allison, Pathologic Fractures.
- Dr. Willard D. White, Results in Fracture of the Spine.
- Dr. Arthur A. Zierold, Newer Methods of Determining Extent of Traumatic Brain Injury.
- Dr. George D. Eitel, Fracture Dislocation of the Shoulder.

NEBRASKA

Society News.—A symposium on medical care of families of low income was presented before the Omaha-Douglas County Medical Society, Omaha, November 13, by Drs. Rudolph Rix, John R. Kleyla, John Jay Keegan and Frederick O. Beck. —Dr. John Alexander, Ann Arbor, Mich., delivered the annual Alpha Omega Alpha address at the University of Nebraska College of Medicine, Omaha, November 26.

Fifty Years in Practice.—Dr. and Mrs. Peter Harold Salter, Norfolk, were guests of honor at a dinner sponsored by the Madison-Six Counties Medical Society at the Hotel Norfolk, November 2, in honor of Dr. Salter's fiftieth anniversary of medical practice. Dr. Morris Nielsen, Blair, was toastmaster. Dr. Salter is a native of Canada and received his medical education in Toronto and Edinburgh. He was president of the Nebraska State Medical Association, 1909-1910, and was a founder of the Elkhorn Valley Medical Society.

NEW MEXICO

Personal.—Dr. Charles A. Mozley, Albuquerque, has been appointed health officer of Sandoval County and Dr. Hilton W. Gillett, Lovington, for Lea County.

Malaria Control Projects.—FERA drainage projects for malaria mosquito control are under way in Santa Fe, Rio Arriba, Mora and Sierra counties, and projects have been submitted for San Juan and Doña Ana counties.

NEW YORK

Annual Registration Due January 1.—Every practitioner of medicine and surgery in New York is required by law to apply annually, on or before January 1, to the secretary of the board of medical examiners for a certificate of registration, on application forms furnished by him, and to pay at that time a fee of \$2. The law authorizes the secretary of the board to permit secretaries of duly incorporated medical societies to act as his representatives to receive and transmit to him such applications and fees. Practitioners are liable to severe penalties for failing to register and for continuing in practice thereafter.

Exhibit on Medical Progress.—Progress in medicine during the last century was shown in a varied exhibit at Rochester's Centennial Exposition recently. A committee, of which Dr. Stearns S. Bullen was chairman, prepared the exhibit with the cooperation of the University of Rochester School of Medicine, the Rochester Hospital Council, the Genesee Valley Nursing Association, the Rochester Tuberculosis and Health Association, the health bureau and the Temporary Emergency Relief Administration. Among the displays were exhibits depicting pioneer medicine, early medical instruments and modern medical paraphernalia. There were slides showing the development of hospitals and the history of surgery, transparent pictures illustrating prevention and treatment of tuberculosis and the use of the x-rays in diagnosis, and charts showing the increase in life expectancy and the activities of the Medical Society of the County of Monroe. One physician contributed a display of foreign bodies removed from lungs, throats and ears; health agencies showed preparations used in the control of communicable disease. The development of the human infant was portrayed in a series of actual embryos, and another group of pathologic specimens showed organs attacked by various diseases. In addition, there were exhibits on food and sanitation, old medical books and child health in Rochester.

New York City

Honorary Membership in the Academy.—The New York Academy of Medicine at a meeting November 8 awarded honorary memberships to the following scientists: Sir Humphry D. Rolleston, Surrey, England; Dr. August Krogh, Copenhagen, Denmark, Nobel prize winner in 1920; Dr. Claude Regaud, Pasteur Institute, Paris; Dr. William H. Howell, physiologist, Baltimore, and Dr. Frederick George Novy, professor of bacteriology, University of Michigan Medical School, Ann Arbor.

Medical College News.—At the opening session of the Long Island College of Medicine, October 1, Dr. Morgan Willcox Ayres, Upper Montclair, N. J., presented three paintings to the college. One was a portrait of his father, Dr. Daniel Ayres, one of the founders of the college in 1858. The other two are copies of paintings by Sir Joshua Reynolds of Dr. John Hunter and Sir Astley Cooper. Dr. Frank L. Babbott Jr., president of the college, accepted the paintings. Dr. Babbott also announced completion of a new recreation building presented to the college last year by the Misses Jennie and Cornelia Donnellon, who have since died.

Hospital News.—Dr. George R. Brighton has been appointed attending otolaryngologist to Roosevelt Hospital, succeeding Dr. Hampton P. Howell, who resigned after twenty-two years at the head of the department. —The Bronx Hospital held a clinical conference on orthopedics, with presentation of cases of interest to the general practitioner, November 14. Members of the staff who presented cases were Drs. Sigmund Epstein, Maurice H. Herzmark, Abraham B. Pemsler, Aaron Schwartz, Samuel W. Boorstein, Louis Saltzman, David Sashin and Sidney H. Freilich. —Dr. David Adlersberg of the University of Vienna gave a lecture at Mount Sinai Hospital, November 3, on "Modern Trends in the Dietetic Treatment of Diabetes Mellitus."

Personal.—Dr. Charles Diller Ryan, clinic executive of the Payne Whitney Clinic, New York Hospital, has been appointed administrative consultant in psychiatry to the department of hospitals. —Dr. Karl Landsteiner of the staff of the Rockefeller Institute for Medical Research received the honorary degree of doctor of science from Cambridge University, England, October 22. —Dr. Harry Wessler has been appointed chief of the tuberculosis division of the Montefiore Hospital and its country sanatorium, succeeding the late Dr. Maurice Fishberg. —Dr. William H. Park was honored by an achievement award given by the Alumni Association of Columbia University graduate schools, November 12. —Walter F. Gobel, Ph.D., has been promoted from associate to associate member of the staff of the Rockefeller Institute for Medical Research; Drs. Frank L. Horsfall, John W. Murray and Albert B. Sabin have been appointed assistants.

NORTH DAKOTA

Annual Registration Due January 1.—Every practitioner of medicine and surgery holding a license to practice in North Dakota is required by law to register annually on or before January 1 with the secretary-treasurer of the board of medical examiners and at that time to pay a fee of \$5 if a resident of North Dakota or \$2 if a nonresident. A practitioner may not lawfully practice if he has not registered. If he does so his license may be revoked and can be reinstated on the payment of unpaid fees and 50 cents for each month of default.

OHIO

State Director of Health Appointed.—Dr. Walter H. Hartung, Toledo, has been appointed state director of health by the incoming governor, Martin L. Davey, who takes office January 14. Dr. Hartung, a graduate of Toledo Medical College in 1912, has served two terms as coroner of Lucas County and ran for mayor of Toledo in 1933. He succeeds Dr. Harry G. Southard.

Academy Awards Prize for Poetry.—Dr. Wenzel A. Medlin has been adjudged winner of a poetry contest conducted by the Cleveland Academy of Medicine and declared first poet laureate of the society. Dr. Medlin was awarded a silver cup for a lyric poem of three stanzas entitled "Darrow Hills." Thirty-two poems were entered in the contest, in which Mrs. Katherine Kelley Taylor was the judge. Honors for excellent work also went to Drs. Roy G. Pearce, Akron (nonresident member), Horace E. Mitchell, Lakewood, Torald H. Sollmann, Frank J. Vokoun and Samuel L. Leinel.

District Meetings.—At a meeting of the Union Medical Association of the sixth councilor district in Wooster, November 7, speakers were Drs. Donald D. Shontz, Massillon, on "Treatment of Auricular Fibrillation"; William H. Bunn, Youngstown, "Recognition of Common Cardiac Irregularities"; Roy Wesley Scott, Cleveland, "Coronary Artery Disease," and David Steel, Cleveland, "Roentgen Diagnosis of Syphilitic Aortitis and Unusual Types of Thoracic Aneurysm."—The Eighth District Medical Society held its annual fall meeting in New Lexington, November 1, with the following speakers: Drs. Charles W. McGavran, Columbus, on "Problems Relating to the Colon"; Julien E. Benjamin, Cincinnati, "Present-Day Conceptions in the Prevention of Heart Disease," and Frank W. Harrah, Columbus, "Urology from the Standpoint of the General Practitioner."

Personal.—Dr. Abram L. Van Horn, Cleveland, has been appointed chief of the division of child hygiene of the state department of health. The department has been without a director for two years because of curtailments in the budget.—Dr. Samuel B. Kistler, Coshocton, has been appointed health officer of Coshocton County to fill the unexpired term of the late Dr. David M. Criswell.—Dr. Harry G. Sloan, Cleveland, received the honorary degree of doctor of science from Washington and Jefferson College, Washington, Pa., recently. Dr. Sloan is a graduate and has for several years been a trustee of the college.—Dr. Francis M. Frazier, Bryan, who is also a lawyer, was recently elected judge of the court of common pleas in Williams County.—Dr. Ernst J. Oesterlin, Milwaukee, has been appointed pathologist to the Springfield City Hospital.

PENNSYLVANIA

Annual Registration Due January 1.—Every practitioner of medicine and surgery holding a license to practice in Pennsylvania is required by law to register annually, on or before January 1, with the board of medical education and licensure in the department of public instruction, and to pay a fee of \$1 or such fee as may be fixed by the department of public instruction. A practitioner who fails to register and who continues to practice is liable to a fine of from \$10 to \$100.

Society News.—Dr. Robert S. Dinsmore Jr., Cleveland, addressed the Luzerne County Medical Society, Wilkes-Barre, November 7, on results of malignant disease.—Dr. Paul D. White, Boston, addressed the Cambria County Medical Society, Johnstown, December 6, on "Important Problems in Cardiovascular Diagnosis and Their Treatment."—Brig. Gen. Matthew A. Delaney, commandant of the Army Medical School, Carlisle Barracks, addressed the Dauphin County Medical Society, Harrisburg, December 2, on "What the United States Army Has Contributed to the Progress of Medicine." Drs. Oscar Paul Holmer and Howard K. Petry of the staff of the Harrisburg State Hospital addressed the society in November on "Child Guidance in Its Relation to Medical Practice" and "The Community Relation of a Mental Hospital," respectively.—Drs. George W. Ramsey and John B. McMurray, Washington, were speakers at a meeting of the Fayette County Medical Society, Uniontown, December 6, on "Rheumatic Heart Disease and Subacute Bacterial Endocarditis" and "Differential Diagnosis of Lateral Sinus Thrombosis, Meningitis and Brain Abscess," respectively.

Philadelphia

Seminars on Cardiovascular Disease.—The current group of graduate seminars sponsored by the Philadelphia County Medical Society deals with cardiovascular disease. Speakers for the series are Drs. John Eiman, Charles C. Wolferth, Henry C. Bazett, James E. Talley and Eugene M. Landis.

Presentation of Dental Library.—The administrators of the will of the late L. Aslley Faught, D.D.S., presented his dental library of more than 1,000 volumes to the Philadelphia County Medical Society at a meeting, November 21, in the auditorium of the society. Dr. Faught's son, Mr. Albert Smith Faught, made the presentation; Dr. Seth A. Brumm, president of the society, accepted the gift for the society and Dr. James M. Anders for the library committee. After the ceremony members inspected the library. Dr. Faught, who died about a year ago, was professor of operative dentistry at Temple University for many years. He was the father of Dr. Francis Ashley Faught.

Society News.—Dr. DeForest P. Willard delivered the annual oration of the Philadelphia Academy of Surgery, December 3, on "Relationship of the Parathyroid Gland to Calcium Metabolism." Dr. Benjamin Lipshutz also presented a paper on "An Incision for the Exposure of the Ventral Surface of the Distal End of the Radius and Its Related Structures."—Drs. Douglas Macfarlan and Robert F. Ridpath, among others, addressed the Philadelphia Laryngological Society, December 4, on "Ionization Treatment in the Ear—Present Status," and "Agranulocytic Leukemia," respectively.—The Obstetrical Society of Philadelphia devoted its meeting, December 6, to a discussion of the recent report and recommendations of the maternal mortality survey of Philadelphia. Various phases of the subject were presented by the following speakers: Drs. Jesse O. Arnold, the laity; Barton C. Hirst, the physicians; Clifford B. Lull, the hospitals, and William R. Nicholson, organized medicine.—The meeting of the Philadelphia County Medical Society, December 12, was devoted to a general consideration of fractures for the benefit of the practicing physician. Participants in the program were Drs. Hubley R. Owen, Eldridge L. Eliason, John Royal Moore and Harvey C. Masland.

SOUTH DAKOTA

Society News.—A recent meeting of the Yankton District Medical Society was addressed by Dr. Jacob A. Bargen, Rochester, Minn., on "Management of the Various Types of Colitis." Drs. Francis J. Abts, Yankton, and Joseph C. Ohlmacher, Vermillion, discussed thymoma.—Dr. C. Frederick Rodda, Minneapolis, addressed the Aberdeen District Medical Association recently on acute abdominal conditions in children.

Health Officers' Meeting.—The annual meeting of the South Dakota Health Officers' Association was held at Huron, November 14. Dr. Jay Arthur Myers, Minneapolis, was the guest speaker, giving an address on tuberculosis before the association and another at a public meeting. Among other speakers, Dr. A. S. Rider, Flandreau, president-elect of the South Dakota State Medical Association, discussed "Medical Society Organization."

TEXAS

Annual Registration Due January 1.—Every practitioner of medicine and surgery holding a license to practice in Texas is required by law to register annually on or before January 1 with the state board of medical examiners and at that time to pay a fee of \$2. If a practitioner fails to renew his registration within sixty days after January 1, his license is suspended.

Dallas County Condemns State Medicine.—The Dallas County Medical Society at a meeting, October 25, adopted a resolution condemning all forms of socialized medicine and participation of the government or lay agencies in the practice of medicine except in cases of necessity. The resolution also condemned mass examination of school children, expressing the belief that such examinations should be made in the physician's office. The members pledged themselves by this action to make these examinations and to institute such measures of prevention as are practicable and acceptable to the parents and to take no part in "wholesale, unscientific, unsafe free examinations, or wholesale preventive measures applied without previous individual study of children." They further pledged themselves to see that no section of the public is neglected because of inability to pay. This resolution was prepared by the president of the state medical association.

UTAH

Hospital Cancer Committees.—Four Salt Lake City hospitals have formed special cancer committees during recent months to work with the standing cancer committee of the Utah State Medical Association. Each committee consists of a surgeon, an internist, a pathologist and a radiologist and in

some cases additional members. At the Salt Lake General Hospital members of the committee are Drs. Orin A. Ogilvie, George A. Cochran, Robert J. Alexander and James P. Kerby; at the Latter-Day Saints Hospital they are Drs. Leland R. Cowan, Ralph T. Richards, William R. Tyndale, Quince B. Coray and Lyman L. Daines; at Holy Cross they are Drs. John J. Galligan, Fuller B. Bailey, Laurence N. Osman, James P. Kerby and Thomas A. Flood, and at St. Marks Hospital Drs. Orin A. Ogilvie, William L. Rich and Charles W. Woodruff. The plan is to study all tumor material entering a hospital, compare the pathologic with the clinical diagnosis, the time elapsing between the time the patient first noticed any symptoms and the first visit to the doctor, and to study treatment and its results.

VERMONT

Society News.—Dr. Ira I. Kaplan, New York, addressed the Rutland Medical and Surgical Society, November 6, on "Malignant Lesions of the Lip, Tongue, Pharynx, Larynx and Esophagus." Dr. Edward M. Livingston, New York, addressed the society, October 23, on "Acute Appendicitis: Its Symptomatology and Differential Diagnosis."—Dr. William R. Morrison, Boston, addressed the Northwestern County Medical Society at Newport recently on "Modern Conceptions of Stomach Surgery."

GENERAL

Lumbermens Mutual Casualty Company Abandons Flat Rate Plan.—Information has been received following the publication of a letter by Dr. W. C. Nordholz in *THE JOURNAL*, November 24, page 1641, that the Lumbermens Mutual Casualty Company, Chicago, has abandoned its flat rate plan for medical service in relationship to noncompensable industrial cases.

Jacobi Fellowship for Women Physicians.—The Women's Medical Association of New York City offers the Mary Putnam Jacobi fellowship of \$1,000 for graduate work abroad in the medical sciences to any woman graduate of an approved medical school. Each candidate must be endorsed by the head of the department in which her previous work has been done, and the recipient must give full time to the study of her problem. Applications should be filed with the secretary of the committee, Dr. Rose Cohen, 36 West Ninetieth Street, New York, by April 1, 1935. They should be accompanied by statements as to health, educational qualifications and the problem proposed for investigation.

Prize Offered for Essay on Goiter.—The American Association for the Study of Goiter again offers the Van Meter prize of \$300 for the best essay on goiter, based on original research, preferably on the basic cause. The prize essay or an abridgement is to be presented at the annual meeting of the association in Salt Lake City, Utah, in June 1935. Competing manuscripts should be in the hands of the corresponding secretary, Dr. William Blair Mosser, Kane, Pa., not later than April 1, 1935. The prize for 1934 was awarded to M. A. B. Brazier, Ph.D., London, England, for her essay on "The Impedance Angle Test for Thyrotoxicosis." Honorable mention went to Prof. Ugo Cerletti, Genoa, Italy, and Dr. Roy McCullagh, Ph.D., Cleveland.

Health at Wilmington and Nashville.—Telegraphic reports to the U. S. Department of Commerce from eighty-six cities with a total population of 37 million, for the week ended December 1, indicate that the highest mortality rate (19.1) appears for Nashville, Tenn., and Wilmington, Del., and the rate for the group of cities as a whole, 10.9. The rates for Nashville and Wilmington for the corresponding period last year were 16.1 and 14.7, respectively, and for the group of cities, 11.4. The annual rate for eighty-six cities for the forty-eight weeks of 1934 was 11.3 as against a rate of 10.9 for the corresponding period of the previous year. Caution should be used in the interpretation of these weekly figures, as they fluctuate widely. The fact that some cities are hospital centers for large areas outside the city limits or that they have a large Negro population may tend to increase the death rate.

Meeting of Orthopedists.—Dr. Charles LeRoy Lowman, Los Angeles, was chosen president-elect of the Western Orthopedic Association at its second annual meeting in Los Angeles, November 9-10. Other officers are Drs. Lionel D. Prince, president; Merrill C. Mensor, secretary, and Howard H. Markel, treasurer, all of San Francisco. The next meeting will be held in the San Francisco Bay district. The organization of a chapter for the northern district of Washington and Oregon was unanimously approved. Dr. Walter Mosauer, Los

Angeles, was the guest speaker at the banquet, Friday evening, his subject was "Anatomy and Mechanics of Snake Locomotion." Other speakers on the program included:

Dr. Ernest W. Cleary, San Francisco, Simple Devices for Application of Traction to Fractures of Forearm and Leg Bones.
Dr. Charles L. Hawk, Hollywood, Treatment of Chronic Osteomyelitis.
Dr. Brooks P. Stephens, Oakland, Orthopedic Problems of Ameliasis.
Dr. Ward M. Rolland, Los Angeles, Supracondylar Fractures of the Elbow.

Southwest Society Opposes Health Insurance.—The Medical and Surgical Association of the Southwest, embracing Arizona, New Mexico, Western Texas and northern Mexico, at its annual meeting in El Paso, November 22-24, adopted resolutions opposing the establishment of national health or sickness insurance and endorsing the principles adopted by the House of Delegates of the American Medical Association at the Cleveland session. The resolution recommended that the government pass the problem of medical relief arising out of the present depression to the organized medical profession for solution, together with such legal powers and authority as may be necessary. It was asserted that the adoption of health and sickness insurance schemes represents an adjustment to an economy of poverty, whereas the problem in America is an adjustment to an actual or potential economy of abundance. The establishment, therefore, of yet another poverty-born device will serve to hinder rather than facilitate our adjustment and can have no logical justification, it was stated. Dr. James J. Gorman, El Paso, was chosen president-elect of the association, and Dr. David M. Davis, Phoenix, Ariz., became president. Drs. Chester R. Swackhamer, Superior, Ariz., and John G. Moir, Deming, N. M., were elected vice presidents and Dr. William Warner Watkins, Phoenix, secretary. The 1935 meeting will be held in El Paso.

Society News.—Dr. Edward S. Hatch, New Orleans, was elected president of the Clinical Orthopedic Society at its annual meeting in St. Louis, November 9-10. Dr. Philip Hoffmann, St. Louis, was chosen vice president and Dr. James E. M. Thomson, Lincoln, Neb., secretary. Next year's meeting will be held in Indianapolis and Louisville, Ky., dates to be selected later.—Dr. William L. Clark, Philadelphia, was reelected president of the Academy of Physical Medicine at its annual meeting in New York, October 30-31. Among features of the meeting were a symposium on the rôle of electricity in surgery presented by Drs. William D. McFee, Boston, William L. Clark, Philadelphia, Grant E. Ward, Baltimore, Lester R. Whitaker and Benedict F. Boland, Boston; an address by Prof. Isidore Gunzburg, Antwerp, Belgium, on "The European Concept of Physical Medicine," and the presentation of an honorary fellowship to Dr. Robert Tait McKenzie, sculptor and research professor of physical education, University of Pennsylvania, for his "achievement in physical education and sculpture and his notable contribution to the rehabilitation of maimed soldiers during the World War."—At the annual meeting of the American Society of Tropical Medicine, November 16, Dr. Henry E. Meleney, Nashville, Tenn., was chosen president-elect, and Dr. Edward B. Vedder, Washington, D. C., was installed as president. Dr. Alfred C. Reed, San Francisco, was reelected secretary. The dates for the next annual session were tentatively set for Nov. 13-14, 1935.

Government Services

Pediatrician Appointed Assistant Chief of Children's Bureau

Dr. Martha M. Eliot, associate clinical professor of pediatrics at Yale University School of Medicine and for several years director of the division of maternal and child health in the Children's Bureau of the U. S. Department of Labor, has been appointed assistant chief of the bureau in charge of all matters relating to health. Dr. Eliot, a graduate of the Johns Hopkins University School of Medicine, Baltimore, has carried on investigations on growth, nutrition, rickets and diet, with emphasis on the preventive and economic aspects of the problems. She was made instructor in the pediatric department at Yale in 1921, assistant clinical professor in 1927 and associate clinical professor in 1932. At present she is attending pediatrician to the New Haven Hospital and New Haven Dispensary. She has been on the staff of the Children's Bureau since 1924. Among other medical affiliations, Dr. Eliot is a member of the American Pediatric Society; the American Academy of Pediatrics, in which she is chairman of the committee on child health relations, and the National Research Council.

The Radium Treatment of Cancer

The report of the Medical Research Council on the medical uses of radium has just been published. The outcome of the research in radium therapy initiated by the Council has helped toward the stabilization of methods and shown that the reactions of the tissues to this form of radiation is most complex and bewildering. While certain of the responses of isolated forms of cell life may be comparatively simple, a very different behavior is shown by tissues that form part of a connected organized structure, and nowhere is this seen better than in the reactions of malignant tumors both to radium and to the x-rays. Even in the simplest living structures the reaction to radium cannot be readily explained or described.

Three varieties of malignant disease (other than skin cancer) offer the most promising field for the use of radium: uterine, buccal and breast cancer.

CANCER OF THE UTERUS

There is little apparent difference in the technic of the treatment of uterine cancer at the chief centers in this country and in the world at large. What is usually aimed at is local treatment with radium supplemented by x-rays to the pelvis. Comparison with the results of surgery show two important points: Frankly operable cases are treated just as successfully by radium as by surgery, but with a much smaller mortality, while inoperable cases give under radium a by no means negligible percentage of clinical cures—apparent freedom from disease for five years. Therefore an increasing number of gynecologists refer their patients for radiotherapy rather than submit them to operation.

CANCER OF THE MOUTH

In buccal cancer it has been a general relief to surgeons to know that, for primary lesions of the tongue, radium is successful in proper hands. At most radium clinics, comparatively little difficulty is felt in dealing with primary growths of the tongue by radium treatment, either interstitial or by means of larger units of 1 Gm. and upward applied externally. The trouble is with secondary growths in the glands. At present there seems to be an even balance of opinion between surgical removal and irradiation, either interstitially or externally by radium and x-rays.

CANCER OF THE BREAST

In breast cancer the position is still more problematic. Owing to its success in early cases, surgery will probably be followed for many years yet. But, in view of the fact that the proportion of success is small once the axilla is invaded, there is need for exploring radiologic methods to the utmost. The methods of interstitial radiation have been used, but the breast is not a favorable site because of the presence of so many important nerves and blood vessels, damage to which is so easy and made good with such difficulty. X-rays are probably the most suitable agent, and if the work of Coutard can be continued on a comprehensive scale, a big step forward will be made. In this country surgery and radiology are used almost to an equal extent in breast cancer, and the chief contributions to the treatment by radium have been initiated here. At the centers in St. Bartholomew's Hospital and Aberdeen the practice for some time has been as follows: The primary growth, with the probable extensions in the axilla and neighboring glands, is treated with interstitial radium. After the lapse of six or eight weeks the primary growth is removed and

examined by pathologists to see the effect of the gamma radiations. Under certain definite conditions of irradiation, comparatively little actively growing growth is left. Of seven patients treated in this way at Aberdeen in 1932, five remain well.

The centers supplied with radium by the Medical Research Council comprise six London hospitals—the Middlesex, University College, St. Bartholomew's, St. Peter's (for genito-urinary diseases), Marie Curie (staffed by women physicians), Royal Free (the London School of Medicine for Women) and St. George's—and hospitals at Birmingham, Cardiff, Aberdeen and Dublin. Manchester does not participate in the council scheme but receives a considerable amount of radium from the Radium Commission, and workers in its center receive grants for study in certain lines of treatment and in biologic problems. Research into the best methods of estimating radium dosage is being carried out at the Radium Institute of Manchester. This is on original lines and promises to be of considerable practical value.

The Scientific Refugees from the German Persecution

In a letter to the *Times*, Lord Rutherford, president of the Academic Assistance Council (formed to assist scientific refugees from the German persecution) reports progress. Of the German scholars and scientists displaced since April 1933, 200 have found permanent places and 325 have been provided with temporary facilities for continuing their research outside Germany. This means that at least two thirds of the total number who are justified in hoping to continue their scientific work have been assisted to remain in the academic world. The activities of the academic assistance committees have been coordinated on an international basis, and the size and nature of the problem are now known.

The Academic Assistance Council is at present giving emergency grants to seventy-one scholars and scientists in the universities of this country to maintain them while seeking permanent posts. Of the scholars to whom the Council made grants before April 1934, approximately one third have found positions outside this country. The council is convinced that this absorption will continue, provided the emergency grants in aid can still be given. But there is danger of the funds being exhausted before permanent placement is achieved. Some national committees on the continent are already faced with collapse, and the resources of the Academic Assistance Council will be brought to an end in July 1935 by its present commitments.

The council has decided that its emergency work of grants in aid, payment of traveling expenses and loans for reestablishment must continue, but that in addition it should make a more permanent contribution to the defense of academic freedom by the creation of a limited number of research fellowships available at the British universities for scholars and scientists of special standing in their subjects. For this purpose and for the continuance of its urgent emergency work the council proposes to issue an appeal for funds. The council has never, in principle, confined its emergency assistance to those displaced from Germany alone, and it proposes that the fellowships shall be available for scholars and scientists in any country who are unable to continue their work for reasons of religion, political opinion or race. For a constructive program of assistance on an international basis there is already the prospect of obtaining from an American source funds for the creation of thirty-six fellowships of three years' duration available in the universities of the British dominions.

Obligatory Medical Examination Before Marriage

In the house of lords, Lord Kilmaine moved that the marriage laws should be so amended as to make it obligatory for both parties to produce medical certificates of fitness before they

come before a minister of religion or the civil authority. He referred to many cases of men and women leading spoiled lives through no fault of their own but owing to some hereditary taint. He proposed that there should be four kinds of certificates. Certificate A would be the "all clear," stating that the parties were perfectly fit to marry and raise a family. Certificate B would show that for some reason of health there should be delay, and the parties could present themselves again after six months. Certificate C would say that the parties could marry without danger to each other, but that it should be a childless marriage. He held strongly that it was wicked to bring children into the world unless there was a reasonable prospect of their being able to lead healthy, happy and useful lives. This implied that some form of birth control must be employed. Certificate D would prohibit the marriage entirely. It would be used in cases in which there was danger not only to the children but to the contracting parties.

The bishop of Norwich opposed the motion. He said that there was a dignity attached to the human race which must never be lost sight of. Failure to obtain a certificate would not always prevent alliances from which children would result. The archbishop of Canterbury dwelt on the practical difficulties of the proposal. In the case of certificate C, how was the impossibility of procreation to be ensured? For the government, Viscount Gage said that the Ministry of Health regarded the proposal as a matter of some importance. He did not think that any serious consideration had been given by the public to limitation of the right to marry except in the case of mental defectives. The attitude of the Ministry of Health was that there was sufficient evidence from experience to justify the testing of public opinion thoroughly in regard to the reports of the Board of Control (the body which controls lunacy administration) and the Departmental Committee on Sterilization. These reports recommended the voluntary sterilization of mental defectives. It was realized that there were undeniable evils, some of which might be prevented, but it was felt that in these delicate matters it was necessary to carry public opinion. To proceed on the lines proposed by Lord Kilmaine without large evidence of public and medical support would be disastrous to the cause he had at heart. The motion was by leave withdrawn.

PARIS

Dec. 13, 1934.

Social Insurance Law Unpopular

There is much discontent in French medical circles and an active discussion is taking place as to what can be done to bring the medical profession into line with the rapid changes taking place in organized society, especially since the World War. Clinics, controlled and directed by groups of physicians, as they exist in the United States, are practically nonexistent not only in France but all over Europe. A series of letters in a recent issue of one of the Paris journals reveals the opposition of those who hesitate to abandon the traditions of medicine and the fervent plea of the more progressive physicians to adapt themselves to the social evolution and establish diagnostic centers under private control. The French social insurance law is not very popular, either with those whom it protects against illness and old age or with the medical profession. It differs, however, from similar legislation in Germany in permitting the assured to choose his own physician, who must adjust his charges to a fixed government tariff. The establishment of diagnostic centers all over France by the profession is one solution of the question before the government steps in to organize this method of extending the benefits of modern medicine.

Phlebitis and Embolism Following Gynecologic Operations

In the October 20 issue of the *Progrès médical*, Macias de Torrès, a prominent Spanish surgeon, submitted his experience based on 2,000 major gynecologic operations. There were twenty-five cases (1.25 per cent) of phlebitis affecting the lower extremities, and seven embolisms. More than half, fifteen of the twenty-five cases of phlebitis, were in women over 40. Operations for uterine fibroids constituted more than one third (36 per cent) of those, followed by phlebitis. He agrees with the generally accepted opinion that infection as the direct result of the operation, or latent infection in the removed structures or as the result of trauma during the operation, only exceptionally has any part in postoperative phlebitis or embolism. These complications are rare following salpingectomy of infectious origin but are common after myomectomy or removal of large cysts or after operations for extra-uterine pregnancy. Preceding generalized infections, especially influenza, may have some influence but not a very important one. Anemia as the result of metrorrhagia or cardiovascular changes is certainly an important etiologic factor.

A series of cases was studied to see whether changes in the coagulation time of the blood had any influence. From extensive coordinated laboratory and clinical observation it would appear that it is impossible at present to tell in which patients a phlebitis is likely to appear after operation. The preoperative use of vaccines does not act as a prophylactic, as maintained by some French gynecologists. The administration of cardiac stimulants, perfect asepsis, unnecessary traumatizing of tissue, and a good operative technic are the only measures that might aid in decreasing the possibility of the development of phlebitis. Getting the patients out of bed early is still a debatable prophylactic. He allows the patient to get up on the tenth day, at which time the sutures are removed from the abdominal wall.

In 2,000 laparotomies for gynecologic conditions there were seven (0.35 per cent) fatal embolisms. In some nonfatal cases the pulmonary embolism is often erroneously diagnosed as a bronchopneumonia. Of all the causes of embolism, such as varicose veins, anemia, age, and operations by the vaginal route, the most important factor according to de Torrès appears to be the age of the patient. Of the seven patients, five were above 40, one was 38 and one was much younger. In conclusion, a good operative technic is the only measure that will tend to prevent postoperative thrombosis and embolism.

Typhoid, Shellfish and Fuel Oil

At the October 16 meeting of the Academy of Medicine of Paris, Drs. Loir et Legangneux of Havre read a paper on typhoid, shellfish and fuel oil. The presence of several large oil refineries at this seaport and the constant discharge of fuel oil from steamers caused the authors to study how this can affect the shellfish, especially mollusks and clams, which live along the shores near such a harbor. The immediate cause of this investigation was an epidemic of typhoid this fall, which could be traced to the ingestion of shellfish.

They carried out some experiments to determine how the oil acts on such shellfish.

They found that mollusks absorbed some of the fuel oil, as was evident from the odor and the fact that the mollusks appeared pale and ill nourished.

They studied the effects of fuel oil on typhoid and paratyphoid cultures, which were examined every two hours. No inhibitory action was observed in the development of the cultures. One can best explain infection following the ingestion of shellfish (mollusks, clams and oysters) by the fact that they are rendered incapable of defending themselves against the

development of typhoid and paratyphoid bacilli because of the toxic action of the fuel oil. Clams are more dangerous than any other shellfish, because the clam lives so near the surface of shallow water that it is more likely to have its defensive mechanism of ejecting organisms rendered inert by the fuel oil floating there. The conclusions reached were that the oil per se is not very toxic but leads to a cellular degeneration even when only small quantities are ingested by the mollusk or clam. This places the latter at a disadvantage in trying to struggle against the organisms.

Influence of Exercise on Metabolism

Guy-Laroche, Chaisemartin and Grigaut made some interesting observations on twenty-one army officers during a six weeks intensive training period. No restrictions of diet were required. The first effect noted was an increase in weight in fifteen of the twenty-one. Cholesterol can be considered as an index of fat metabolism as well as that of lipoids in general. When the percentage in the blood is higher than normal, the combustion of these lipoids is delayed in the organism. Examination of the blood revealed a normal figure and remained so in fifteen of the twenty-one. In nine others the percentage was above normal at the beginning but decreased markedly during the six weeks observation period.

The better functioning of the tissues and viscera was followed by a decrease in the blood urea and uric acid, which was especially noticeable in the case of those whose uric acid in the blood was above normal at the beginning. It is essential not to fatigue the individual and to increase the severity of the exercises gradually. Sports and physical culture should be supervised medically in order to avoid the harmful effects of fatigue.

This agrees with the views expressed at the International Congress of Physical Education and Sports held last September in Chamonix, France. It was voted at this congress that special courses be given in medical schools and a diploma be granted at the end of these courses.

Inoculation of Rabbits with Cerebral Tissue in Dementia Paralytica

Bessemans of Ghent University, Belgium, reported his observations at the Academy of Medicine on the inoculation of cerebral tissue obtained during life and at necropsy from a case of dementia paralytica. All the tests for syphilis were positive during life. The cerebral tissue was obtained during a decompression operation. Although the latter was followed by temporary improvement, death occurred thirty-eight days later. More cerebral tissue was obtained for inoculation of rabbits and guinea-pigs at the necropsy, held eight and one-half hours after death. In both instances the animals failed to develop lesions, even though at the first series of inoculations *Spirochaeta pallida* was demonstrated as being active. These experiments show that the spirochete of dementia paralytica is incapable of giving rise in the rabbit, either directly or indirectly by the intermediary of the guinea-pig or of other rabbits, to specific lesions like those caused by the ordinary *Spirochaeta pallida*. Bessemans is of the same opinion as Levaditi, that the spirochete of dementia paralytica is a special form with elective localization for the nervous tissue of man, such that its original pathogenic properties differ from those of the ordinary *Spirochaeta pallida*.

Responsibility in Abortion

An interesting verdict as to the responsibility of a physician in relation to criminal abortion has just been rendered by the court of appeals, to which a decision of a lower court had been referred. A young woman, believing herself to be pregnant,

asked a physician to perform an abortion. He refused but gave her the address of a woman who would comply with her request. The physician also aided by instructing the applicant how to find the abortionist without attracting the attention of the janitor of the apartment house, who in Paris is indirectly the representative of the police. Both the lower and the appeals court decided that the physician was just as responsible for the abortion, in simply indicating where it could be done, as though he himself had performed it. The law in France is very strict in such cases and the physician will be subject to from two to five years of prison and a heavy fine.

Liver Function Tests in Nervous Disorders and in Opiate Addiction

Dr. K. Hang of Rostock made liver function tests on patients with polysclerosis, on patients who had had encephalitis and on opium addicts. He made the galactose test, determined the urobilinogen in the urine and occasionally made the test with sodium phenoltetrachlorophthalein and determined the quantity of bilirubin in the serum. In about half of the cases of multiple sclerosis and in nearly all patients with the striatal syndrome there existed disturbances in the carbohydrate fixation capacity of the liver and (less often) disturbances of the pigment metabolism. Similar disturbances of the hepatic function were observed in opium addicts, morphine addicts and in persons who had been given morphine-scopolamine for longer periods and in larger doses, so far as they had withdrawal symptoms. If these were not present or if a diet rich in carbohydrates and deficient in fats and in proteins was prescribed, the metabolic disturbances were less severe or were entirely absent. Such a diet, that is, an antiacidotic one, is the best in morphinism in general, but particularly during and after withdrawal, because it appears to be effective in counteracting the acidosis of morphinism. Functional disturbances of the liver were observed also in a case of codeine addiction but not in an addict to eucodal. The blood sugar, determined during fasting, was regularly rather high or above normal in morphine addicts. By "dehydrochol acid" the blood sugar could be somewhat reduced, the urobilinogenuria could be counteracted, and in some instances the carbohydrate tolerance could be somewhat increased. The same could be observed in parkinsonism and (but less pronounced) in multiple sclerosis. After treatment with liver extracts, by mouth or by injection, the blood sugar (determined on the fasting stomach) increased in the addicts but likewise in parkinsonism and generally also in multiple sclerosis; the urobilinogenuria decreased as a rule or disappeared entirely. The galactose hyperglycemia changed hardly at all in opiate addicts and in patients with parkinsonism, whereas in patients with polysclerosis the carbohydrate tolerance increased as a rule. Liver preparations and "dehydrochol acid" exerted no influence on neurologic conditions, but there was an improvement in the general condition and in the turgor of the tissues. For this reason the two remedies may eventually effect remissions in multiple sclerosis; and in morphine addicts and in persons with the striatal syndrome they may act as general stimulants. The treatment of the striatal syndrome by atropine or by scopolamine reduced the urobilinogenuria but increased the blood sugar content and left the galactose tolerance of the persons with the striatal syndrome generally unchanged. The demonstrated disturbances of the hepatic function in opiate addicts, in multiple sclerosis and probably also in the striatal syndrome are most likely the results and not the cause of the disturbance in the central nervous system.

Bacteriologic Relations between the Appendix and the Oral Cavity

In recent years the department of Professor Gins in the institute for infectious diseases in Berlin has conducted experiments that have clarified the bacterial flora of the teeth, by the cultivation of about twenty former unknown anaerobic organisms without spores. It seemed natural to employ this method also for other tissues. The appendix was chosen because conditions may be expected in its mucous membrane that are favorable for the development and preservation of anaerobic bacteria. The observations thus far have been made on eight surgically removed appendixes, some of which were from acute and some from chronic cases. It was found that the cultivation of non-spore bearing anaerobic bacteria failed in only a single experiment. In all other instances *Leptotrichia*, streptobacilli, pneumosintes, *Bacterium melaninogenicum*, *Fusiformis* or *Vibrio* were produced in pure culture. Approximately ten types that were found were identical with forms that were already known to occur in the oral cavity. Nothing definite can be said as yet about their significance in the pathogenesis of appendicitis. At any rate it is worthy of note that, in the microscopic picture of the smears from the mucous membrane of some of the examined cases, certain formerly not cultivable threadlike bacteria predominated. In the critical evaluation of the observations that were made in these experiments, numerous forms of anaerobic Actinomycetes that appeared in the cultures were disregarded, since their occurrence seems to be almost universal, a fact that so far has not been demonstrated with regard to the other types. Nothing is yet known about the time of the first appearance of the non-spore bearing anaerobes in the appendix, but Gins assumes that, in analogy to the oral cavity, they invade the appendix during early youth. In future studies these types should be given especial attention, since some of them, particularly *Leptotrichia*, may be pathogenic.

Action of Dichlorethylsulphide (Yellow Cross—Mustard Gas) on the Skin

Among the poison gases of the World War, it was the "yellow cross" (mustard gas) that became especially well known. Its peculiar action, namely, the relatively late appearance of the clinical manifestations and the lasting action on the skin, was extremely annoying. Whereas the gradual development of the macroscopic change had been carefully studied, information about the changes within the tissue itself were still lacking. Doerffel and Pöpping of Königsberg, therefore, studied macroscopically and microscopically the course of corrosion of the skin with the mustard gas (dichlorethylsulphide) on animals and compared with it corrosions produced by mineral acids. The corrosives employed for these experiments were undiluted dichlorethylsulphide and its solutions in benzene (1:10, 1:50, 1:100), fuming nitric acid, concentrated sulphuric acid and so on. The exposed portions of the skin were excised after ten minutes, after one, two, six and twelve hours, after one, two, three, six and nine days, and finally after two and three weeks until the process had completely healed. Following the corrosion there developed characteristic changes in the epithelium and in the cutis. A pronounced edema develops in the epidermis and in the cutis, and this within a comparatively short time leads to a subepithelial formation of blisters. The vessels are dilated, and some are plethoric and are surrounded by a perivascular mantle of infiltration (eosinophilia). These changes extend widely beyond the originally corroded focus. Corrosions produced by mineral acids present entirely different aspects. Here develops at the corroded site a drying and shrinking of the tissues, which finally leads to a wedge-shaped shedding of the necrotic region of the skin with a line of demarcation. The changes resulting from mustard gas resemble greatly those produced by x-ray burns.

ITALY

Sept. 15, 1934.

The Lombard Surgical Society

The Società Lombarda di chirurgia met recently in Milan under the chairmanship of Professor Donati, director of the surgical clinic of the University of Milan. Rotolo spoke on typhoid peritonitis, after having examined the records of 5,300 necropsies carried out at the Institute of Pathologic Anatomy in Milan. Of the 117 fatal cases of typhoid, in seventeen cases, or 14.5 per cent, there was diffuse peritonitis due to perforation; one case presented a circumscribed peritonitis due to perforation; two cases, peritonitis due to rupture of a suppurative infarct of the spleen, one case due to perforation of a typhoid ulcer. There were twenty-three deaths due to early peritoneal complications, or 19.4 per cent.

Pellegrini dealt with early surgical operations in acute appendicitis. Since the advantages of an early operation are indisputable, he suggested that a special publicity campaign to that end be carried on among the physicians and the general public.

Alberti used intensive radiotherapy in a grave case of post-operative recurrence of sarcoma of the thyroid region, accompanied by metastases of the bony skeleton, to the right tibia and to the femoral diaphysis of the same side. The treatment consisted in the simultaneous application of three casts containing a total of about 290 mg. of radium and kept in position for about three weeks. The reaction was violent, with anemia, fever and asthenia, but the final result was the disappearance of the recurring focus in the neck and the domination of the two metastatic foci in the bones, with complete restoration of the bone destroyed by the tumor, which gradually regained its normal structure. The patient has enjoyed excellent health during the past three years. The speaker took account of the notable changes brought about—particularly in the blood—by the absorption of such an especially large quantity of radiation, and since such changes were then followed by a complete restoration of the normal conditions, he urged his colleagues not to overestimate the damage and the dangers associated with intensive radium therapy and to regard with less skepticism in such cases the possibility of an effective radium treatment.

In the treatment of postoperative duodenal fistulas, Pecchia and Peracchia secured excellent results by using insulin. They hold that this condition is associated with a dysfunctioning of the pancreas, which is accompanied ordinarily by duodenal fistulas and which is the cause of a change in the carbohydrate metabolism. Insulin promotes the cure of the fistulas by reestablishing the exchange of hydrocarbons and acting on the gastric secretion and on the external pancreatic secretion. The speakers are of the opinion that this treatment, combined with hypodermic and intravenous administration of large quantities of dextrose and chlorides in fluid form, is sufficient to bring about a recovery from duodenal fistulas. They recommend this treatment also for the reason that it does not contraindicate other methods of treatment that might be desirable in some cases.

A New Center for Combating Sterility

A center for the diagnosis and treatment of sterility has recently been established at Milan under the supervision of the Cassa edile per le assicurazioni sociali. For two years the problem of childless marriages has received special attention with the aid of the abundant clinical material. The president of the Cassa has now decided to combine and coordinate the activity of its various specialized sanitary organizations in a single center, the aid of which is offered gratuitously not only to its members but also to any one desiring to discover the nature of sterility.

Poisons Used with Suicidal Intent

Meneghette of Trieste has studied the various types of poison used for suicidal purposes. There is a widespread opinion that at various epochs a suggestive factor difficulty of analysis plays a part in the choice of a poison. The accidental and the criminal poisonings do not present much psychologic interest. His observations show that, whereas in the remainder of Italy for every 45 cases of suicide by poisoning there are 100 by firearms, in Venezia Giulia (Trieste) the respective relation is 150:100. During the first two decades of this century the poison most commonly used was corrosive mercuric chloride. Of late the employment of barbiturates has become widespread.

Scrotal Ring of Domrich

Favaro of Modena has spoken before the Surgical Medical Society of this city on the results of his research on the scrotal ring of Domrich (1927), which, he maintains, is none other than the "money bag" (paunch) of Girard (1823) and of the French topographic anatomists of the last century. This condition concerns a thickening of the superficial fascia and of the deep layer of the subcutaneous tissue which lies anteriorly to the opening that communicates below with the third inguinal ring. McGregor demonstrated the third ring in 1928 but did not take cognizance of the work of Domrich. Posteriorly the ring is circumscribed by a similar thickening of the subcutaneous tissue. According to the author, the spermatic cord is often caught at the root of the scrotum as the result of irregular thickenings of the subcutaneous tissue, forming altogether a scrotal inguinal ring.

Vital Statistics

From the monthly bulletin of the Istituto centrale di statistica, it appears that, on March 31, 1934, the resident population of Italy was 42,868,000. The number of new-born for the first five months of the current year (440,100) is greater by 8,795 than that for the same period in 1933 and constitutes 10.4 per thousand inhabitants. The excess of living births over deaths was thus 192,078.

Cabinet Approves Sanitary Laws

The cabinet recently approved the new sanitary laws. The trend has been to make the powers of the sanitary authorities more effective, and to exert a supervision and control over every activity that aims to promote the public health. The cabinet approved also new rules pertaining to the granting of rewards for meritorious civil services. These regulations provide also for the bestowal of medals on those scientists who, in the research laboratories, risk their lives for the welfare of mankind.

RIO DE JANEIRO

(From Our Regular Correspondent)

Oct. 15, 1934.

Bacteriology of Leprosy

Dr. H. C. de Souza Araujo recently presented before the members of the Academia Nacional de Medicina the results of his experiments on the bacteriology of leprosy, on which he has worked about six years. In spite of the fact that typical acid-alcohol-fast organisms have been isolated from leprosy material of either human or murine origin and indexed as *Mycobacterium leprae*, there are bacteriologists who still wonder whether or not those organisms are the etiologic agents of leprosy. In the official collection of leprosy cultures of the Lister Institute of London, under the numbers from 509 to 522 the following specimens of *Mycobacterium leprae* appear: Kedrowsky, Rost and Williams, Nabarro and Bayon, Clegg I and II, Duval's Chrome, Levy-Chrome, Brinkerhoff I and II, Lepra 8, Barry, Reenstierna, Gurrie and Elly. There is the genus *Mycobacterium*, created by Lehmann and Neumann in

1896, and the genus *Coccithrix* (*Coccithrix leprae*), created by A. Lutz in 1886. Even today Lutz defends the priority of the creation of *Coccithrix* over *Mycobacterium* and the advisability of adopting his genus. During the conference on Leprosy in Manila in January 1931 the members accepted the designation *Mycobacterium leprae*, first genus of the *Mycobacteriaceae* (Chester, 1901), second family in the order of the *Actinomycetales*, under the class of *Schizomycetes*, for the etiologic agent of leprosy. The tendency of modern mycologists is to include in the *Mycobacterium* genus all, or at least the majority, of the specimens of mycobacteria of the *Actinomyces* genus (Harz, 1877), which heretofore have been considered as the third genus of the *Actinomycetaceae* family (Buchanan, 1916). In this connection Drs. Kedrowsky, Brulowa, Platanov and some others reported in 1928 results of experiments during which they observed bacterial mutations in old cultures of tubercle bacilli and of *Mycobacterium leprae*. In the same year the speaker reported results of experiments during which he isolated a pure culture of *Actinomyces* (*A. lepromatis*) from leprosy material. This fact was corroborated in 1932 by Tomas Ocaña of Argentina in four cases of florid leprosy. The speaker has a complete collection of cultures of *Mycobacterium leprae*, with the various specimens of which he has worked from 1928 to date. Some of his experiments have not as yet been reported. Besides the cultures from the English and American collections, he has the following: cultures of the *Streptothrix leproides* of Devke, discovered by J. M. Gomes, which are used as an antigen in the test for deviation of the complement in leprosy; those of the Instituto de Hygiene of São Paulo, which are of great value in early diagnosis of leprosy; Acosta I and II, isolated by F. L. Acosta from lepers in Bogotá, and samples isolated in Assumpção by Luiz Migone.

The results obtained by the speaker while he was working with Kedrowsky's culture, one of the best of the collection, and probably the one that has been recently used in the preparation of a new antileprosy vaccine, confirmed those reported by Fraser and Fietchez in the *Lancet* in 1915. He reported negative results from Shiga's method in 1932 and from Loewenstein's method last year. Ota's cultures from Japan lived but a short time in the speaker's laboratory and he was unable to perform any experiments with them. Soule was unable to send him some of his cultures, because they were so scanty that they sufficed to cover only his own work in immunology. He expects to work in the near future with cultures from Vienna (Loewenstein) and from the University of California (Walker). The speaker discussed Lobel's work, as it appears in the book "*Leprosy of Buffaloes*," Lobel's veterinary doctoral thesis. Lobel reports a disease in buffaloes, of which he studied twenty-one cases in Java. The disease was named tubercular leprosy in buffaloes, because of its resemblance to human tubercular leprosy. It begins by the appearance of erythematous spots in the skin, which evolve into confluent cutaneous nodules in which an acid-fast organism, similar to Hansen's bacillus, is found in great numbers. The histopathology of the disease is also similar to that of human leprosy. Leper cells with globoid bodies are always present in the nodules. Lobel refused the hypothesis of tuberculosis. The study of this new morbid entity in animals with which the natives of Java live in so close promiscuity, since they are the only beasts of burden and almost the only means of transportation in a city in which the endemicity of leprosy is so high, may open new horizons in the pathogenesis of leprosy.

Blastomycosis in Brazil

Dr. Florino de Almeida, assistant head of the laboratory in the department of microbiology of the Faculty of Medicine of São Paulo, recently lectured before the Sociedade de Medicina e Cirurgia on the etiology of blastomycosis in Brazil. He

reviewed the large number of fungi that have been classified as etiologic agents of blastomycosis and focused his studies on *Coccidioides immitis* and *Paracoccidioides brasiliensis*, two varieties related to the Brazilian disease. One case was reported from Argentina and various cases from the United States caused by *Coccidioides immitis*. This mold was incriminated for a long time as the etiologic agent of Brazilian cases of blastomycosis. The speaker stated that the North American and the South American varieties are different, both in their biology and in their morphology. Both fungi show remarkable morphologic differences in the lesions. The speaker, after a review of the literature, projected films showing the clinical aspects of blastomycosis and the characteristics of the etiologic agents.

AUSTRALIA

(From Our Regular Correspondent)

Oct. 19, 1934.

Malaria in Australia

A third of Australia lies within the tropical zone. In the tropics too are Papua and the Mandated Territory of New Guinea. Before the coming of the white man, tropical Australia was probably malaria free but, like Mauritius in the last century, it became infected. Happily, the resulting endemicity has not been of grave extent except in a few scattered areas and instances. In Papua and New Guinea it is otherwise. Malaria is a factor of great importance, which enters in one way or another the daily life and work of every resident. Malaria has never seriously interfered with tropical settlement in Australia as it has done in nearly every other tropical area. There is no evidence to suggest that malaria existed in Australia prior to its early settlement. The disease was imported from overseas. It was first reported in 1838 at Port Essington in the Northern Territory of Australia. The first medical description was given in 1867 by Dr. J. A. White, who described the fevers of the Gulf of Carpentaria in Queensland. In Burketown, which is on the gulf, in 1864 the population was annihilated by the "black sickness," which was probably introduced by Malays coming across in proas. This was almost certainly malignant malaria. In general it might be said that malaria is nowhere endemic in Australia below the tropic of Capricorn. Sporadic cases of indigenous origin have indeed occurred in New South Wales and Southwestern Australia and have occasioned considerable anxiety and alarm, but in general the disease is confined to the narrow coastal strip that borders Australia's million square miles of tropical territory; i. e., to the northwest coast of Western Australia, the Northern Territory, the coastline of the Gulf of Carpentaria, Cape York Peninsula, and the northern Pacific slope as far south as Cairns and Innisfail (19° S.). These areas are popularly regarded as endemic centers.

So far as the vector is concerned, Heydon has definitely incriminated *Anopheles punctulatus* by dissection and experiment, for the Territory of New Guinea, while in the absence of proof, *Anopheles annulipes* is hypothecated for Australia, on account of its preponderance of numbers in malarious localities. The occurrence of isolated "epidemics" or "flare ups" of malignant malaria in the endemic area has been a feature of the history of malaria in Australia. The subject is of topical interest at the moment on account of a sharp epidemic in the Kimberley region of Western Australia. The epidemic can be traced to an outbreak near Wave Hill in July 1933, which smoldered away among the station blacks and their nomadic brethren till with the wet season of 1934 it broke into flame and destroyed 200 natives and a dozen white men. The discussion of malaria cannot be complete without reference to the effective control of malaria that is now being maintained in Darwin and the Northern Territory by Dr. Cook. The chief

strength of his method is to ensure adequate treatment of every case. His efforts to convey medicine and instructions to sufferers embraces the airplane, the camel and the bush mail.

State Ministry of Health Forecast for Queensland

The serious nature of the epidemic of Weil's disease revealed the lack of organization in the state health department in Queensland. Opportunity was taken to appoint Dr. R. W. Cilento as director general of health and medical services. Dr. Cilento's appointment is an important development in what is intended to be a thorough reorganization of the health and local authority administration. The director general will be given control not only of the hospitals and medical services, aborigines, insanity and aged people's homes but also of health services now covered by other departments. Dr. Cilento is highly qualified for the position. He has done valuable work in New Guinea, where he was director of public health. He was director of the Australian Institute of Tropical Medicine at Townsville in 1921 and 1928 and was subsequently the director of the division of tropical hygiene. In the course of his work he has been associated with the hookworm campaign (partly financed by the Rockefeller Foundation), the control of leprosy, chronic nephritis, and dietary problems in New Guinea.

Cremation in Australia

The rate of increase in cremations is greater in Australia than in any other part of the world. With a population of seven million, there are six crematories in operation. The figures for other countries are Germany 109, United States 87, Great Britain 25, Switzerland 20, Denmark 12, Czechoslovakia 11, Sweden 10, France 6 and Norway 5. During the past twelve months there have been three crematories established in Australia, two in New South Wales, and one in Queensland. These have all been of modern design, the Queensland crematory using an electric furnace giving a temperature between 2,000 and 2,500 F. In the Sydney (Rockwood) crematory there were 138 cremations in 1926. In 1933 there were 1,367. At the Melbourne crematory there were 84 in 1928 but this total had increased to 263 in 1933. One aspect of cremation that appeals to the public is that the cost is £10. This is much less than the average cost of a grave site, its preparation, monumental work and maintenance. Religious opposition is evident by the Roman Catholics. The cremation regulations require two medical certificates to be provided before cremation can take place. One views the increasing adoption of cremation with approbation. Even in a young country like Australia, whose history extends over a mere century (Melbourne celebrates its centenary this week), the areas of ground occupied by cemeteries seem unduly large. In Tasmania the cemeteries surround the churches. With the expansion of the great cities, the necessity has frequently arisen for bodies to be disinterred and the cemetery area used for other public purposes.

New Zealand Controls Contraceptives

Legislation has been introduced into the New Zealand parliament to restrict the sale of contraceptives to registered chemists and only to persons over 18 years of age. The use of automatic vending machines is prohibited, as is also the offering for sale in a street or public place. Illuminated signs must not be used for the advertising of contraceptives, but displays can be made within the chemist's shop provided such are not visible to passers-by. The act defines contraceptives as "any chemical or mechanical means for the deliberate restriction of conception."

Epidemic of Weil's Disease in North Queensland

Since October 1933 an epidemic of Weil's disease, or spirochetal jaundice, has been in existence in North Queensland among the sugar cane fields around Ingham. There have been 134 cases and six deaths. The disease has run its usual course

of jaundice, gastric disturbance and multiple hemorrhages. *Leptospira* has been demonstrated, and cultures from the urine of the patients and the kidneys of rats caught in the epidemic area have been positive. Ingham has an average yearly rainfall of 78.56 inches, taken over forty-two years, and during the early months of the epidemic the rainfall was three times the monthly average. Rat infestation is a serious problem in this area. Pollution of the ground and other unhygienic practices of the cane cutters make difficult the epidemiologic control. This is the first time this disease has been recognized in Australia. It is expected that the epidemic will become widespread, as infected rats have been identified over a wide area.

Anthrax from Shaving Brush

A case of anthrax has occurred in Canterbury, New Zealand, as a result of using an imported shaving brush understood to be of Japanese origin. Several similar cases occurred in Melbourne ten years ago.

Marriages

ANDREW B. WHITAKER, Camden, S. C., to Miss Alice Irving Ball of Pine Orchard, Conn., at New Haven, Conn., October 24.

ERNEST WILLIAM BLANCHARD, Traverse City, Mich., to Miss Lillian Swingley of Cincinnati at Covington, Ky., November 12.

RUDOLPH MAXIMILIAN GOEPP, Philadelphia, to Miss Elizabeth Alma Louise Wenning of Nashville, Tenn., October 6.

SIDNEY WILLIAM WATSON, Alexis, Ill., to Miss Margaret Powers of St. Paul, at Bowlers, Minn., November 3.

ALFRED PARKER SMITH, Winchester, Tenn., to Miss Sara Knox McDowell in South Pittsburg, September 21.

SHELBY WILLIAM VANCE, Pineola, N. C., to Miss Frances Elizabeth Hudson of Cartersville, Va., October 25.

WALTER HARRIS KETCHUM JR., Jacksonville, Fla., to Miss Dorothy Alice Dodd in Atlanta, Ga., October 13.

PHILIP A. CAULFIELD, Washington, D. C., to Miss Grace Tumulty in Spring Lake, N. J., September 22.

CLARENCE OLSON, Princeton, Ill., to Miss Ola Mae Dilts of Michigan City, Ind., in Chicago, November 1.

WILLIAM HUTSON PRIOLEAU to Miss Sarah Whitehead Parsons, both of Charleston, S. C., in November.

JAMES KIRBY HOWLES, New Orleans, to Miss Mildred Ione Dunn of Baton Rouge, La., in November.

LEWIS FOX FRISSELL, New York, to Mrs. Ethel Hope Bennett in Newport, R. I., September 27.

ESTHER ELIZABETH SMUCKER, Morton, Ill., to Mr. John Hodel at Tiskilwa, Ill., November 4.

OSCAR J. MICHAEL, Danville, Ill., to Miss Pauline S. Smith of Bridgen, Ont., Canada, October 20.

HOWARD STEPHENS, Mentor, Ohio, to Miss Lenora Rimpes of Cleveland Heights, November 9.

CYRIL J. RADL, Pardeeville, Wis., to Miss Ruth Armstrong of Wauwatosa, November 10.

JACOB C. LEONARD JR. to Miss Mary Louise Moffitt, both of Lexington, N. C., October 20.

EDWARD J. CALLAHAN, New York, to Miss Emma Jessup of Essex Fells, N. J., July 1.

MADISON H. BUCKLEY, Martin, Tenn., to Miss Sue Margaret Moore of Dresden, recently.

OLIN A. ELLIOTT to Miss Pauline Zaayer, both of Des Moines, Iowa, August 31.

GEORGE A. DUNCAN, New York, to Miss Kathryn E. Hewitt of Baltimore, recently.

SARKIS H. KASH, Cudahy, Wis., to Miss Dorothy Amman of Racine, November 10.

HARRY JACOBS, Brooklyn, to Miss Celia Hornung of Corning, N. Y., November 29.

JAMES E. ORR to Miss Margaret James, both of Seneca, S. C., October 24.

JOHN L. BUNDY to Miss Laura Yorke, both of Rock Hill, S. C., October 19.

ADNER WOLF to Dr. ANNE ROBINSON, both of New York, November 24.

Deaths

Edward Dix Fisher, New York; University of the City of New York Medical Department, 1878; in 1911 member of the House of Delegates of the American Medical Association and in 1911-1912 Chairman of the Section on Nervous and Mental Diseases; professor emeritus of neurology, University and Bellevue Hospital Medical College, assistant to the chair of materia medica, 1881-1884, instructor in diseases of the nervous system, 1884-1885, lecturer in the department of nervous diseases, 1885-1888; adjunct professor of medical jurisprudence and psychological medicine, 1888-1890, adjunct professor of nervous diseases, 1891-1892, adjunct professor of nervous diseases, medical jurisprudence and psychological medicine, 1892-1893, professor of mental and nervous diseases, 1893-1898; upon the consolidation of the medical department of New York University with the Bellevue Hospital Medical College in 1898, he became professor of diseases of the nervous system and served until 1906 was professor of nervous and mental diseases in 1906-1924 and professor of neurology in 1924-1928, when he became professor emeritus; member of the Medical Society of the State of New York and the Association for Research in Nervous and Mental Diseases; past president of the American Neurological Association and the Medical Society of the County of New York; at various times on the staffs of the Bellevue, Willard Parker and St. Vincent hospitals; aged 78; died, November 23, of cerebral arteriosclerosis.

Cornelius Godfrey Coakley ☉ New York; University of the City of New York Medical Department, 1887; professor of otolaryngology, Columbia University College of Physicians and Surgeons; lecturer in anatomy, 1889-1890, and instructor of histology, 1889-1896, at his alma mater; clinical professor of laryngology, 1898-1905, and professor, 1905-1914, University and Bellevue Hospital Medical College; member of the American Laryngological Association and the American Otolological Society; fellow of the American College of Surgeons; consultant in otolaryngology, Babies, Bellevue, Sea View, Woman's, Sloane, Skin and Cancer and Southampton hospitals and the New York Infirmary for Women and Children; author of "Diseases of the Nose and Throat"; aged 72; director and attending otolaryngologist, ear, nose and throat service, Presbyterian Hospital, where he died, November 22, of heart disease.

John Walter Carmack ☉ Indianapolis; Indiana Medical College, School of Medicine of Purdue University, Indianapolis, 1907; in 1934 elected Secretary of the Section on Laryngology, Otolaryngology and Rhinology of the American Medical Association; clinical professor of rhinology, otology and laryngology, Indiana University School of Medicine; member of the American Academy of Ophthalmology and Oto-Laryngology, American Laryngological Association, and the American Laryngological, Rhinological and Otolological Society; fellow of the American College of Surgeons; surgeon to the Robert W. Long Hospital, James Whitcomb Riley Hospital for Children, Indianapolis City, Methodist Episcopal and St. Vincent's hospitals; aged 49; was killed, December 5, in an airplane accident.

Arthur Monroe Mendenhall ☉ Indianapolis; University of Pennsylvania School of Medicine, Philadelphia, 1909; professor of obstetrics, Indiana University School of Medicine; member of the American Association of Obstetricians, Gynecologists and Abdominal Surgeons and the Central Association of Obstetricians and Gynecologists; fellow of the American College of Surgeons; member of the school board for seven years, school medical inspector for five years and health officer of Jamestown, R. I., in 1916; on the staffs of the Robert W. Long, Indianapolis City and Florence Crittenden hospitals, William H. Coleman Hospital for Women, Methodist Episcopal, St. Vincent's and Christian hospitals; aged 50; was killed, December 5, in an airplane accident.

Hampton Lansden Fancher ☉ Chattanooga, Tenn.; University of the South Medical Department, Sevanee, 1899; in 1926 member of the House of Delegates of the American Medical Association; at one time professor of gynecology at his alma mater; fellow of the American College of Surgeons; past president of the Tennessee State Medical Association and the Chattanooga and Hamilton County Medical Society; medical director of the Provident Life and Accident Insurance Company; for many years on the staffs of the Erlanger Hospital; aged 61; died, November 12, of pneumonia.

Percy Todd Phillips, Santa Cruz, Calif.; Western Reserve University Medical Department, Cleveland, 1889; member and past president of the California Medical Association; past president of the Nevada State Medical Association and the

Santa Cruz County Medical Society; member and past president of the California State Board of Medical Examiners and past president of the Nevada State Board of Medical Examiners; fellow of the American College of Surgeons; on the staff of the Hanly Hospital; aged 66; died, October 28, of chronic myocarditis.

Arnold Sturmdorf * New York; College of Physicians and Surgeons in the City of New York, Medical Department of Columbia College, 1886; fellow of the American College of Surgeons; associate surgeon to the Woman's Hospital, consulting gynecologist to the Manhattan State Hospital and the Jewish Memorial Hospital, New York, and the Brownsville Hospital, Brooklyn; consulting surgeon to the Community Hospital, New York, and the Williamsburg Maternity Hospital, Brooklyn; aged 72; died, November 13, of coronary occlusion.

Philip Michael Grausman * New York; Columbia University College of Physicians and Surgeons, New York, 1900; served during the World War; fellow of the American College of Surgeons; director of surgery, Gouverneur Hospital, where he had served in various grades for nearly twenty-four years; director and chief surgeon to the Hospital for Joint Diseases and attending surgeon to the Lebanon Hospital, New York; consulting surgeon to the Beth Israel Hospital, Newark, N. J.; aged 58; died, November 21, of acute coronary thrombosis.

Leroy Thompson, Chicago; Hahnemann Medical College and Hospital, Chicago, 1908; fellow of the American College of Surgeons; consulting oculist and aurist of the Illinois Bell Telephone Company and chief consultant in ophthalmology and otology of the Illinois State Industrial Commission; on the staffs of St. Luke's and the Illinois Masonic hospitals; formerly chief of the staff of the Illinois Eye and Ear Infirmary; aged 51; died, November 14, in Bath, N. Y., of carcinoma.

Standish McCleary * Baltimore; College of Physicians and Surgeons, Baltimore, 1890; professor of histology and special pathology at his alma mater, which later became the University of Maryland School of Medicine and College of Physicians and Surgeons, where he was professor of pathology and clinical medicine; on the staff and member of the board of the Mercy Hospital and on the staff of the University Hospital; aged 64; died, November 19, of coronary thrombosis.

Victor Ray Sr. * Cincinnati; Miami Medical College, Cincinnati, 1897; emeritus professor of ophthalmology, University of Cincinnati College of Medicine; member of the American Academy of Ophthalmology and Oto-Laryngology; past president of the Cincinnati Academy of Medicine; formerly director of the department of Ophthalmology, Cincinnati General Hospital, and on the consulting staff of the Good Samaritan Hospital; aged 68; died, October 25, of heart disease.

David Charles Strong, Upper Lake, Calif.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1902; member of the California Medical Association; fellow of the American College of Surgeons; at one time physician in charge of the San Bernardino (Calif.) County Hospital; on the staff of St. Francis Hospital, San Francisco; aged 55; died, September 8, of coronary occlusion and mitral insufficiency.

Alvin Walter Baird * Portland, Ore.; Cornell University Medical College, New York, 1905; past president of the Portland City and County Medical Society; at one time assistant professor of surgery, University of Oregon Medical School; member of the North Pacific Surgical Association; fellow of the American College of Surgeons; on the staff of the Multnomah Hospital; aged 68; died, October 10.

Thomas Francis Rockwell, Rockville, Conn.; University of the City of New York Medical Department, 1881; member of the Connecticut State Medical Society; past president of the Toland County Medical Society; veteran of the Spanish-American War; on the staff of the Rockville City Hospital; aged 80; died, October 15, of carcinoma of the rectum.

Samuel McCoy Sproat * Chillicothe, Ohio; University of Michigan Medical School, Ann Arbor, 1913; fellow of the American College of Surgeons; served during the World War; on the staff of the Chillicothe Hospital; aged 45, was instantly killed, November 9, when the automobile in which he was driving collided with a wagon.

Lloyd Melville Sackett, Oklahoma City, Okla.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1903; associate professor of gynecology, University of Oklahoma School of Medicine; on the staffs of the Wesley and University hospitals; aged 54; died, November 12, of pneumonia.

Robert Barnard Slocum, Wilmington, N. C.; Johns Hopkins University School of Medicine, Baltimore, 1905; fellow

of the American College of Surgeons; chief surgeon to the Atlantic Coast Line Railroad; aged 57; died, November 16, in the Johns Hopkins Hospital, Baltimore, following an operation for gallstones.

Clara E. Jones, Goldsboro, N. C.; Woman's Medical College of Pennsylvania, Philadelphia, 1894; member of the Medical Society of the State of North Carolina; for twenty-six years on the staff of the State Hospital; aged 87; died, November 19, of carcinoma of the liver and duodenum.

John Luther Kelly, Oak Grove, La.; College of Physicians and Surgeons, Memphis, Tenn., 1907; member of the Louisiana State Medical Society; served during the World War; member of the state board of health; aged 52; was killed, November 7, in an automobile accident.

John Haggart, Durango, Colo.; Western University Faculty of Medicine, London, Ont., Canada, 1887; member of the Colorado State Medical Society; formerly mayor of Durango; on the staff of the Mercy Hospital; aged 69; died, November 6, in Denver, of carcinoma of the stomach.

William Ferris Curran * Waco, Texas; University of Maryland School of Medicine, Baltimore, 1904; member of the Associated Anesthetists of the United States and Canada; county health officer; aged 61; died, October 15, of cirrhosis of the liver and esophageal hemorrhage.

James Herman Poulton * Springfield, Ohio; Starling-Ohio Medical College, Columbus, 1912; past president of the Clark County Medical Society; served during the World War; on the staff of the Springfield City Hospital; aged 47; died, October 16, of heart disease.

Robert Wesley Randall, Royersford, Pa.; Medico-Chirurgical College of Philadelphia, 1912; member of the Medical Society of the State of Pennsylvania; on the staff of the Pottstown (Pa.) Hospital; aged 44; died suddenly, October 20, of heart disease.

Charles Greenberry Bryant, Jonesville, N. C. (licensed in North Carolina in 1902); veteran of the Spanish-American War; formerly member of the state legislature; aged 69; died, October 16, in the Hugh Chatham Memorial Hospital, Elkin, of cardiorenal disease.

Park Mitchell Barrett * Surg., Lieut. Commander, U. S. Navy; St. Clairsville, Ohio; Georgetown University School of Medicine, Washington, D. C., 1911; entered the navy in 1917; aged 47; was killed, October 8, at Napa, Calif., in an automobile accident.

Harry Woodruff Tittle, New Florence, Pa.; Western Pennsylvania Medical College, Pittsburgh, 1895; member of the Medical Society of the State of Pennsylvania; served during the World War; aged 61; died, November 13, of bronchopneumonia.

Clarence William Baldrige * Iowa City, Iowa; State University of Iowa College of Medicine, Iowa City, 1921; associate professor of theory and practice of medicine at his alma mater; aged 38; was killed, November 22, in an automobile accident.

John Allen Morris, Knoxville, Iowa; Medical College of the State of South Carolina, Charleston, 1929; on the staff of the Veterans' Administration Facility; aged 31; died, October 28, in the Iowa Methodist Hospital, Des Moines, of Hodgkin's disease.

John B. Derrickson * Frederica, Del.; Medico-Chirurgical College of Philadelphia, 1899; past president of the Medical Society of Delaware; director of the Sussex County Health Unit; aged 59; died, October 3, in the Milford (Del.) Hospital.

George Clyde Kneedler * Pittsburgh; Western Pennsylvania Medical College, Pittsburgh, 1892; member of the American Academy of Ophthalmology and Oto-Laryngology; aged 66; died, October 12, of carcinoma of the ascending colon.

Julius Lingenfelder, Hermann, Mo.; Universität München Medizinische Fakultät, Germany, 1889; member of the Missouri State Medical Association; aged 70; died suddenly, November 4, of heart disease and arteriosclerosis.

Albert Isaiah York, Wilton, Maine; Medical School of Maine, Portland, 1898; member of the Maine Medical Association; past president of the Franklin County Medical Society; aged 63; died, October 16, of coronary occlusion.

William Harry Sutton, Midville, Ga.; University of Georgia Medical Department, Augusta, 1908; member of the Medical Association of Georgia; aged 51; was found dead, November 1, of acute dilatation of the heart.

Osmon Cleander Baker Nason, Franklin, Mass.; Boston University School of Medicine, 1891; Harvard University Medical School, Boston, 1901; member of the Massachusetts Medical Society; aged 76; died, October 7.

Walter Theodore Crosby, Manchester, N. H.; Harvard University Medical School, Boston, 1899; fellow of the American College of Surgeons; on the staff of the Sacred Heart Hospital; aged 63; died, September 21.

Elliott W. Kirk, Veedersburg, Ind.; Central College of Physicians and Surgeons, Indianapolis, 1905; member of the Indiana State Medical Association; aged 60; died suddenly, November 6, of cerebral hemorrhage.

John Henry Collenburg, Baltimore; University of Maryland School of Medicine, Baltimore, 1879; aged 82; died, November 13, in St. Agnes' Hospital, of hypertension, arteriosclerosis and cerebral hemorrhage.

Herbert Keith Young, Timmonsville, S. C.; Jefferson Medical College of Philadelphia, 1932; intern at the Bryn Mawr (Pa.) Hospital; aged 26; died, September 28, in the Jefferson Hospital, Philadelphia.

John Richard Parker, Gallatin, Tenn.; University of Louisville (Ky.) School of Medicine, 1893; member of the Tennessee State Medical Association; aged 62; was found dead, November 7, of heart disease.

John Wilbur Chambers, Rudolph, Ohio; Starling Medical College, Columbus, 1894; aged 67; died, November 10, in the Rheinfrank Hospital, Perrysburg, following an operation for appendicitis.

Linus M. Ellis, Washington, Ga.; Atlanta College of Physicians and Surgeons, 1899; member of the Medical Association of Georgia; aged 56; died suddenly, November 1, of cerebral hemorrhage.

Reuben Wesley Mondhank, Lancaster, Ohio; Ohio Medical University, Columbus, 1896; on the staff of the Lancaster Municipal Hospital; aged 59; died, November 12, of Hodgkin's disease.

Edmund Fremont Danford, Glouster, Ohio; Medical College of Ohio, Cincinnati, 1881; member of the Ohio State Medical Association; aged 78; was found dead, November 7, of heart disease.

Peter Randall Powell, Detroit; University of Arkansas School of Medicine, Little Rock, 1908; on the staff of the Grace Hospital; aged 51; died, November 8, of cerebral hemorrhage.

Frederick Joseph Boody, Bishop, Calif.; College of Physicians and Surgeons, Los Angeles, 1913; aged 46; died, September 8, of comminuted fracture of the pelvis and other injuries.

Ephraim Melvin Folsom, Mount Vernon, Ill.; Barnes Medical College, St. Louis, 1896; served during the World War; aged 64; died suddenly, November 7, of heart disease.

Oscar Frederick Collum, McRae, Ga.; Atlanta School of Medicine, 1907; member of the Medical Association of Georgia; aged 52; died, November 14, of heart disease.

Maurice Edward Marlow, New York; Syracuse University College of Medicine, 1924; aged 33; died, November 18, of an overdose of morphine, self administered.

Arthur Henry Stafford, Orlando, Fla.; Detroit Homeopathic College, 1906; served during the World War; aged 53; died, November 8, of cerebral hemorrhage.

William Alexander Campbell, Ponoka, Alta., Canada; Trinity Medical College, Toronto, 1899; aged 61; died, September 1, in Edmonton, of cerebral thrombosis.

William Marcus Peters, Northport, Ala.; Birmingham Medical College, 1906; served during the World War; aged 52; died, October 19, of coronary occlusion.

Henry Otho Lee, Ludlow, Miss.; Mississippi Medical College, Meridian, 1907; Memphis (Tenn.) Hospital Medical College, 1913; aged 55; died, October 15.

Jonas A. Park, Caldwell, Ohio; Ohio Medical University, Columbus, 1895; served during the World War; aged 69; died, October 5, in Columbus, of septicemia.

Louis Frederick Grebe, Reading, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1920; aged 40; died, November 6, of heart disease.

Walter Christian Hirzel, Hidalgo, Texas; Cleveland Homeopathic Medical College, 1902; served during the World War; aged 69; died, October 6.

Augustus E. Perlewitz, Chicago; Hering Medical College, Chicago, 1907; aged 77; died, October 22, of cerebral hemorrhage and arteriosclerosis.

Cyrus Knecht, Matawan, N. J.; Jefferson Medical College of Philadelphia, 1880; aged 83; died suddenly, October 30, in Maplewood, of heart disease.

Robert John Bickel, Fort Wayne, Ind.; Indiana University School of Medicine, Indianapolis, 1931; aged 31; died, November 17, of carcinoma.

John Ira Tucker, St. Joseph, Mo.; Ensworth Medical College, St. Joseph, 1912; aged 54; died, October 7, of influenza and bronchopneumonia.

Joseph Patrick Kelly, Kansas City, Mo.; University of Kansas School of Medicine, 1915; aged 51; died, October 21, of mitral regurgitation.

Grant Porter, Plainfield, Ill.; St. Louis College of Physicians and Surgeons, 1896; aged 62; died, October 20, of carcinoma of the larynx.

Alonzo K. Collins, Birmingham, Ala.; Louisville (Ky.) Medical College, 1890; aged 62; died suddenly, October 30, of heart disease.

Leon Gabriel Sweeney, Scranton, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1911; aged 49; died in August.

James C. Pennington, Andalusia, Ala.; University of Tennessee Medical Department, Nashville, 1894; aged 72; died, September 25.

Oliver Paul Mercer, Indianapolis; Medical College of Indiana, Indianapolis, 1904; aged 58; died, November 11, of heart disease.

John McDermott, Lockwood, Mo.; Barnes Medical College, St. Louis, 1895; aged 69; died, October 23, of nephritis and uremia.

Bureau of Investigation

CLARA ROSS, INC.

Another Medical Mail-Order Fraud Debarred from the Mails

Clara Ross, Inc., was a Missouri corporation organized in 1932 that sold through the mails alleged treatments for "sinus trouble," hay fever and stomach disorders. On Oct. 22, 1934, Judge Karl A. Crowley, Solicitor for the Post Office Department, in a memorandum for the Postmaster General, recommended the issuance of a fraud order against Clara Ross, Inc., because the concern was "engaged in conducting a scheme for obtaining money through the mails by means of false and fraudulent pretenses, representations and promises." On Oct. 30, 1934, the Postmaster General issued such an order.

Clara Ross, Inc., was operated by one Clark F. Ross, president and secretary of the corporation, who did business from a third-floor flat in St. Louis, Mo. Although Clark F. Ross was purporting to treat human ailments, he had no medical or pharmaceutical qualifications; he was essentially a mail-order advertising man. "Clara Ross," whose name was given to the enterprise, was the divorced wife of Clark F. Ross.

In the advertising it was held out that Clara Ross had "suffered untold misery from sinus trouble for seven years" and that she had tried every known method of treatment, but all

ment brought out the fact, obvious enough to physicians, that the Ross treatment for hay fever consisted of ingredients well known to the medical profession, and Ross' representation that "nothing like" that treatment had ever been offered before was false and fraudulent.

The cure for "stomach trouble" that Ross had for sale consisted of his Toxic Poison Eliminator that formed part of the treatments for hay fever and sinusitis, plus a number of white capsules designated "Stomach Conditioner." The latter nostrum was found by the federal chemists to consist of a combination of bismuth subcarbonate, magnesium carbonate, baking soda, chalk, powdered rhubarb, papaya and oil of peppermint. Here again the government's medical experts pointed out that the so-called Ross treatment for stomach trouble was essentially laxative and antacid; that it was not "entirely different" but, as in the case of all the other so-called remedies sold by Ross, the ingredients were well known to the medical profession. The medical men pointed out, further, that what is loosely called "stomach trouble" may be due to a number of causes, including ulcers, cancer, cirrhosis of the liver, gallstones, etc., and that obviously the treatment might vary radically, according to the cause.

Judge Crowley's memorandum also points out that while Ross in his advertising matter laid considerable emphasis on a so-called "Positive No Risk" refund "Guarantee," the government produced evidence to show that in the actual operation of the business the guarantee was uniformly construed in a manner detrimental to the interest of purchasers.

As already stated, the mails were closed to this swindle October 30, this year.

SOME MISCELLANEOUS NOSTRUMS

Elsaco (Electrovita).—"Elsaco" seems to be a later name for what used to be called "Electrovita." Under the old name this nostrum was the subject of an article in this department of THE JOURNAL, Jan. 23, 1932. In August, 1934, Electrovita was declared misbranded under the National Food and Drugs Act because the claims made for it were false and fraudulent. The government chemists reported, as the A. M. A. Chemical Laboratory had previously shown, that the stuff "consisted essentially of diluted lime water."

Indo-Vin.—This nostrum appears to be another "patent medicine" put out by G. H. Mosby, who presumably is the same Mosby who originated "Konjola," from which he was alleged to have made a huge fortune. The Federal Trade Commission issued a complaint against the Mosby Company, but in November, 1933, dismissed the complaint because the company went out of business. Konjola was said to contain "32 different ingredients, 22 of which are Nature's own roots and herbs." Indo-Vin, according to the advertising, "contains 32 ingredients, 22 of which are extracts from the finest medicinal plants." Is Indo-Vin a new name for Konjola?

Catalyn.—Catalyn is a "patent medicine" exploited by the Vitamin Products Company of Milwaukee. It has been advertised under the claim that it would "most effectively restore normal metabolism where abnormality is present," that it "supplies the vital elements necessary for normal functioning of the human system," and that it was to be recommended in cases of goiter, hardening of the arteries, heart trouble, high blood pressure, insomnia and prostate trouble. It was also claimed that acidosis, anemia, Bright's disease, dropsy, enlarged tonsils, menstrual disorders, nervousness, and the "ills of pregnancy" were all particularly responsive to "Catalyn treatment." Other equally preposterous claims have been made for it. Such claims were declared false and fraudulent by the Food and Drug Administration, which seized a quantity of Catalyn in May, 1933. In July, 1933, no claimant having appeared for the Catalyn that had been seized by the government, judgment of condemnation and forfeiture was entered and the court ordered that the product be destroyed (Notice of Judgment 21213, issued August, 1934). According to the government chemists, Catalyn consisted essentially of plant material, including wheat bran, wheat starch, glandular material, including epinephrine, and milk sugar.

SINUS PAIN

I suffered untold misery from Sinus trouble for seven years. Every method known was tried to clear me up; I changed climate three times, had two operations, used special electric appliances, but all failed. Then I located a wonderful treatment, and now my head is clear as a bell. No more 12-hour headaches. No more sleepless nights. I am never bothered a single moment. Write me and I'll gladly tell you how I succeeded in curbing my Sinus misery.

CLARA ROSS, INC.,
3152 Magnolia, Apt. K, St. Louis, Mo.

Typical Ross Advertisement (1933)

failed. Then, according to the advertising, she located a wonderful treatment, and "now my head is clear as a bell." As a matter of fact, Mrs. Ross admitted to the Post Office Inspector who investigated the case that she was not free of sinus trouble, but still suffered from it and expected to continue to suffer from it indefinitely!

The alleged treatment sent out by Clark F. Ross to those who wrote for the sinus-trouble cure consisted of a white powder called "Toxic Poison Eliminator," an olive-colored liquid called "Nostril Cleanser" and an atomizer. The Toxic Poison Eliminator, which was to be taken internally, was found to consist principally of Rochelle salts with a small quantity of phenolphthalein and flavored with oil of cinnamon. The liquid to be used in the atomizer was found by the government chemists to be composed essentially of alcohol and boric acid, with small quantities of sodium benzoate, eucalyptol, methyl salicylate, menthol, sodium salicylate and oil of thyme. Expert medical evidence submitted in the case disclosed, of course, that this combination was not a "wonderful discovery," that it would not and could not bring about complete freedom from sinus trouble, and further, that in certain instances it might prove harmful.

Ross' hay fever treatment was the same as his "sinus trouble" treatment and in addition, a bottle of liquid called "Eye Lotion," a tube of menthol salve referred to as "Nasal Balm," together with a metallic cup for the administration of the Eye Lotion. The federal chemists reported that the Eye Lotion was simply a solution of boric acid and the Nasal Balm was essentially a salve containing menthol. Expert testimony for the govern-

SUBLUXATION OF SACRO-ILIAC SYNCHONDROSIS

To the Editor:—Please give briefly the manipulations necessary to replace a subluxation of the sacro-iliac synchondrosis. Kindly omit name. M.D., Utah.

ANSWER.—Manipulation of the pelvis is analogous to performing the routine examination of these parts more thoroughly than is done for diagnostic purposes. Before this manipulation is carried out, one must rule out tuberculosis, osteomyelitis, acute infectious arthritis, neoplasms, fracture, dislocation and spinal cord tumor. The benefit that follows manipulation is due, in part, to readjustment of the pelvic joints but chiefly to the stretching of the shortened hamstring muscles and tendons.

The chief methods of manipulation are known by the names of Baer, Magnuson, Cox, Nutter and Fisher.

The anesthetic should include (1) hypodermic injection of morphine and atropine one hour before manipulation, (2) induction with nitrous oxide or ethylene, and (3) complete anesthesia under ether. This manipulation can be done under spinal anesthesia.

A most important point in manipulation of the back is protection of the patient's head and neck against any sudden movement.

The patient is placed supine on a low table or preferably on a mat on the floor. On the stretcher are eight hand straps: three on each side and one at each end. As soon as the patient is completely anesthetized, he is lifted by four persons and carefully placed on the floor.

In his first series Baer manipulated 100 patients, with immediate relief in almost every case and with relapse in only three. According to his technic the patient is placed on a low, non-movable table, flat on his back, and then anesthetized. The anesthetization should be carried to the point of complete relaxation of all muscular tissue, for the force to be exerted at times is great and muscular rigidity carries with it some danger to the patient.

While an assistant holds the pelvis firmly, the operator grasps the calf of the leg and flexes the fully extended limb. The hamstring muscles are found to be in a state of spasm. They are attached to the tuberosity of the ischium at their proximal end and to the head of the tibia and fibula at their distal extremity. As the fully extended leg is flexed on the thigh, the hamstring muscles pull on the tuberosity of the ischium and the top of the ilium is pulled backward to meet the sacral junction. This procedure of stretching is carried on until the hamstring muscles are thoroughly relaxed, a condition indicated by the fact that the fully extended leg can be flexed to a position far beyond a right angle; indeed, the dorsum of the foot almost touches the shoulder. A definite click is often heard during the manipulation, which some have thought to be due to a replacement of the misplaced sacro-iliac articulation. Of this, however, Baer was not convinced, for it has seemed that the click is to be heard and felt by a slight subluxation of the head of the femur as it pushes against the hamstring while the leg is in extreme flexion. The presence of the click is always synchronous with the release of the hamstring muscles and indicates that the work has been accomplished. If one now looks at the back, one will find that the flat back has been replaced by a back with a normal lumbar lordosis. Care should be taken in the manipulation, for it is quite conceivable that with careless handling one may obtain a subluxation of the knee joint backward causing a paralysis, or that one may cause a fracture of the head of the femur.

The only two complications that occurred in Baer's series of 100 cases were in one case the setting up of a femoral phlebitis, and in the other, owing to his inability to make a proper diagnosis, the production (some weeks later) of a tuberculous abscess springing from the sacro-iliac joint. After the manipulation has been completed, the patient should be placed on a Goldthwait frame and put up in a plaster dressing extending from the nipple line down to the knee on the affected side. This is done to preserve the lumbar lordosis that has been obtained by the procedure.

The patient is allowed to remain in this cast in bed for a period of ten days, when a small pelvic strap, as indicated for the mild forms, is worn as a preventive measure for the next two months.

Fisher's manipulation is similar to the one of Baer.

In the Magnuson manipulation the patient is placed on his back with the affected half of his body projecting from the side of the table several inches. The affected limb is manipulated as in the Baer manipulation and from this position of hyperflexion is suddenly thrust into the position of hyperextension. The second part of the manipulation consists in locking the hands under the patient's lumbar spine and giving the patient a sudden pull upward in order to increase the lumbar lordosis.

For Cox's manipulation, which is similar to Nutter's, the patient is placed on a table face downward, his weight being supported on the elbows and abdomen and his hands grasping the edge of the table securely. The surgeon, while standing on a box near the feet of the patient, firmly grasps his ankles and lifts his body clear of the table, the body being supported above by the elbows alone. It is held in this manner for several minutes, with the legs in abduction, strong steady traction being made on the affected leg, while an assistant makes firm pressure over the sacrum. The body should be lifted up and down while the traction is being made. There is usually sudden marked relief as the bones slip into place, and the lumbar curvature is in most instances restored at once. The mechanism is as follows:

In lifting the patient's body by the ankles, one hyperextends the spine and thus relaxes the strong posterior sacro-iliac ligaments and also relieves the joint from the pull of the hamstrings. The abduction relieves the supporting action of the psoas muscles. In other words, one places the joint in the position it occupies at the time of displacement, which is hyperextension. The strong pull on the leg of the affected side unlocks the joint by increasing the deformity due to the action of the extensor quadriceps muscles, especially the rectus femoris, sartorius and iliopsoas, which exert a downward and outward pull on the upper anterior part of the ilium, thus increasing the separation from the sacrum and at the same time relaxing the pull from the hamstrings. Reversing the force occurs when the weight of the body drags the spine forward and favors replacement of the ilium by forcing the sacrum forward. This progress is aided by pressure being made over the sacrum by an assistant and by the steady traction on the affected limb, which, as was noted, also tends to unlock or separate the joint. It can be readily seen that the dragging position of the suspended body, together with traction on the affected side, which relaxes the joint, and firm pressure over the sacrum will tend to replace the bones, thus fulfilling Gumm's rule. After replacement, a firm support of adhesive tape is passed behind from in front of one great trochanter to the other. It must be remembered that it is essential to place the support low, well down on the buttocks, below the level of the trochanter, as any lateral pressure above this point tends to separate the joint and produce great pain. The straps should extend from the anterior part of the ilium on one side to a similar point on the other side and should cover the buttock and lower lumbar spine, below the trochanter. A firm pad of cotton or felt over the sacrum will maintain pressure on it at all times. This dressing should be reapplied in about six days. The patient should be put to bed for one week if the displacement is acute, and a small firm pillow so placed as to maintain the lumbar curvature and keep any strain off the injured ligaments.

The following manipulation is recommended by Lewin:

1. Flex the thigh of the unaffected side on the abdomen (knee flexed).
2. Flex the thigh of the affected side.
3. Flex the thigh of the unaffected side (knee extended); do the Lasègue test.
4. Flex the thigh of the affected side till the toes approach the anesthetist's cap.
5. Do the fabere test of the unaffected side.
6. Do the fabere test of the affected side.
7. Stretch the achilles tendon of the unaffected side (if unilateral sciatic pain).
8. Stretch the achilles tendon of the affected side.
9. Stand over the patient, straddling his body, lock both hands under his lumbar spine, and hyperextend the lumbar region.
10. Do the Gaenslen test: unaffected sacro-iliac; affected sacro-iliac.
11. Do the Magnuson manipulation: unaffected side; affected side.
12. Do the Cox manipulation.
13. Then remove the ether mask. Have the patient sit up. Hold his head firmly. Hyperflex the back until his head can be placed between his knees. Bend the back toward the affected side. Bend the back away from the affected side. Repeat 3 and 4.

14. Do straight leg raising: unaffected side; affected side.
15. Strap the entire pelvis. If a good sacro-iliac belt is not at hand, one should strap the entire pelvis with adhesive tape.
16. If it is a unilateral case, leg traction should be applied to the affected side and the foot of the bed elevated.

Some authors do not advise a plaster-of-paris cast but raise the legs or suspend them. Boards should be placed under the mattress. Physical therapy, including radiant heat, massage, diathermy and manipulations, should be started. A pelvic belt can be applied and pelvic traction used. Some patients do well on a curved Bradford frame without traction.

If the displacement of the sacrum appears to be backward, the thigh is flexed as fully as possible with the knee fully extended. This has the effect of rendering the hamstrings tight and, owing to the attachment to the ischium, this portion of the innominate bone is pulled forward, resulting in the iliac bone slipping backward into position on the sacrum.

If the displacement of the sacrum appears to be forward, the patient is placed in the prone position or lying on the side, and the thigh is hyperextended. During this movement the innominate bone moves with the femur owing to the attachment of the Y-shaped ligament of Bigelow, and the ilium slips forward into place. The inquirer should consult:

TREATMENT OF SYPHILIS

To the Editor:—A man, aged 21, weighing 185 pounds (84 Kg.) presented himself with a lesion on the preputial fold, which was eroded, round, indurated and relatively painless. There was a bilateral inguinal adenopathy, more marked on the left. The personal history was unreliable. A dark field examination revealed no spirochetes, and a Meinel test was reported negative. It was nevertheless thought advisable to begin treatment, and eight doses of neoarsphenamine were given five days apart in the following doses: 0.45, 0.6, 0.6, 0.75, 0.75, 0.75, 0.75, and 0.75 Gm. After ten days' rest he was started on mercury inunctions and two weeks later developed a maculopapular eruption on the palms and soles. This was followed soon after by a generalized macular, nonpruritic rash. At the same time he had a sore throat and erosive patches in the mouth, headache, bone pains in the legs and general malaise. The picture was clinically that of secondary syphilis and there was prompt disappearance of all symptoms after two more doses of neoarsphenamine of 0.9 Gm. Was this secondary syphilis? If not, what might it have been? Granted that the patient had syphilis, was the treatment adequate? Is there anything in the literature that describes such an occurrence? In about half of the treatments described a solvent containing sodium thiosulphate was used. Is it possible that this neutralizes the arsenical for the parasite as well as for the host?

M.D., Alaska.

ANSWER:—It would be difficult to describe a case that has been more grievously mismanaged than this; at least six major errors have been committed. Penile lesions should never be treated as primary syphilis on suspicion. The diagnosis must be made by a demonstration of *Spirochaeta pallida* by dark field, the presence of a positive blood Wassermann reaction, or both. Assuming, however, that the clinical diagnosis of primary syphilis was correct, the first course of neoarsphenamine should not have been followed by any rest period, and an insoluble salt of bismuth, given intramuscularly, should have been used in place of mercury by inunction. When the skin eruption and mucous lesions appeared, the diagnosis of delayed secondary syphilis should have been verified either by a Wassermann test of the blood or by the dark field demonstration of the organisms in one of the open lesions.

The clinical description is compatible with the diagnosis of delayed secondary syphilis, but a similar picture might also be caused by erythema multiforme.

Granting that this does represent a relapse with delayed secondary lesions, two further doses of neoarsphenamine are utterly inadequate treatment.

The literature is filled with similar occurrences. A description of this and analogous situations may be found in chapter XXVII (The Arspenamine Resistant and Wassermann Fast Patient) in the recent monograph by Moore, "The Modern Treatment of Syphilis."

The use of a solvent for neoarsphenamine containing sodium thiosulphate is irrational and unnecessary. The therapeutic efficiency of the drug is slightly decreased by this procedure, as is also its toxicity.

It is suggested that from this point on the patient be managed in accordance with the principles set forth in the article by the Cooperative Clinical Group (Stokes, J. H.; Cole, H. N.; Moore, J. E.; O'Leary, P. A.; Wile, U. J.; Parran, Thomas Jr.; Vonderlehr, R. A.; Usilton, Lida J.: Standard Treatment Procedure in Early Syphilis, *THE JOURNAL*, April 21, 1934, p. 1267).

DIAGNOSTIC SIGNS IN LOW BACK CONDITIONS

To the Editor:—Will you kindly explain Lasègue's, Neri's, Mennell's, Demianoff's and Patrick's signs, in reference to differential diagnosis of low back and hip conditions.

M.D., Indiana.

ANSWER:—Lasègue's sign in sciatica is positive when flexion of the thigh on the hip is painless and when the knee is bent such flexion is easily made; this distinguishes the case from hip joint disease.

Neri's sign is a sign of organic hemiplegia, consisting in the spontaneous bending of the knee of the affected side as the leg is passively lifted, the patient being in the dorsal position. The patient being recumbent, his upper extremities are extended and pronated on the examining table: when the forearm is flexed by the hand of the examiner passed under it, the sound forearm remains pronated but the paretic forearm goes into supination.

In eliciting Mennell's sign an examining thumb is placed over the posterosuperior spine of the sacrum and then made to slide, first outward and then inward. If on pressure over the former point tenderness is detected, it is due to a sensitive deposit in the structures of the gluteal aspect of the posterosuperior spine. If the tenderness is over the inner point, it is probable that the superior ligaments of the sacral iliac joint are strained and sensitive. If the tenderness is increased by pressure backward on the anterosuperior aspect of the ilium and decreased by pulling forward the crst from behind, this is positive proof that it is caused by the sensitive ligaments.

Demianoff discusses a sign that permits the differentiation of pain originating in the lumbosacral muscles from lumbar pain of any other origin. The sign is obtained by placing the patient on his back and lifting his extended leg. In the presence of lumbago, this produces pain in the lumbar region, which prevents raising the leg high enough to form an angle of 10 degrees or less with the table or bed on which the patient rests.

In Patrick's test, with the patient supine, the thigh and knee are flexed and the external malleolus is placed over the patella of the opposite leg; the knee is depressed, and if pain is produced thereby arthritis of the hip is indicated. Patrick calls this test fabere sign, from the initial letters of the movements necessary to elicit it: flexion, abduction, external rotation, extension.

WHOOPIING COUGH

To the Editor:—I was called to see a girl, aged 3 years, Sept. 3, 1933, when I obtained a history of a nonproductive cough of two days' duration, which was worse at night. When the patient was seen, the cough was already coming in paroxysms followed by the crowing sound characteristic of pertussis. In addition, the patient vomited all food ingested. There had been two cases of pertussis in the family during the previous month, which I had treated, to one of which the patient had been exposed two weeks previously. Despite the brevity of the prodromal stage, according to the history, therefore, a diagnosis of pertussis was made. This impression was supported by a blood study made the following day, in which the following was found: 12,000 white blood cells, 15 per cent neutrophilic polymorphonuclears, 82 per cent lymphocytes, and 3 per cent eosinophils. A cough plate was not taken. The patient's cough gradually subsided, and when she was seen, Sept. 20, 1934, the cough had almost completely disappeared. September 30 the patient had a slight chill, following which her temperature rose to 102 F. She also began to cough, but when she was examined on the following day the only positive finding was moderately enlarged and congested tonsils. The temperature persisted at about 100 to 101 for a few days and then returned to normal. The cough became steadily worse, however, and on October 7 the cough was coming in paroxysms, at the end of which the patient expectorated thick mucus. The mother told me at this time that the patient had been playing with a boy who had recently developed whooping cough, and she asked me if it was possible that her child had contracted the disease again. A blood count was therefore taken with the following result: white blood cells, 15,000; neutrophils, 16; small lymphocytes, 69; large lymphocytes, 10; large mononuclears, 4; basophils, 1. At present the cough is very severe and of the typical pertussis variety, and the patient vomits all food ingested. Do you believe as I do that this is a case of recurrence of pertussis? If so, how would you account for the fact that the second attack is worse than the first? Have there been other reports of pertussis recurring in the same individual within a short space of time?

ALEXANDER S. WIENER, M.D., Brooklyn.

ANSWER:—It is unfortunate that diagnostic cough plates were not exposed both last year and this year. In a child so young the differential count is not infrequently misleading (the percentage of lymphocytes is naturally high). The clinical evidence of pertussis is more convincing this year than it was last. It is not at all unlikely, however, that the child had pertussis last year and that this year's cough is not due to *Bacillus pertussis* at all but to pathogens that have invaded the same bronchial lining where the pertussis infection was last year. Possibly next year the child might again develop quite a misleading cough. The chill and temperature of 102

at the onset this year are not part of the pertussis. It is not unusual for grandmothers or mothers to contract pertussis a second time (from pertussis children in the household), but it would be extremely rare indeed for a child of 3 to contract pertussis twice.

TREATMENT OF CONGENITAL SYPHILIS

To the Editor:—A baby, aged 5 weeks and weighing approximately 6 pounds, with congenital syphilis, has just come under my care. I am informed that the blood from the cord was Kahn positive. The child has snuffles and a vesicular eruption of the scalp and macular eruption of the buttocks and thighs; also a thin purulent discharge from one eye. There is no enlargement of liver or spleen or other evidence of heredo-syphilis, but both parents are Kahn positive and the mother received only four injections of nearsphenamine during the last trimester of pregnancy. Granting that the diagnosis is correct, what would be the proper course of treatment? Kindly omit name. M.D., Michigan.

ANSWER.—The generally accepted management of the syphilitic infant is as follows:

To begin with, intramuscular injections of 0.025 Gm. of sulpharsphenamine should be given every third or fourth day, for four injections. The dose may then be cautiously increased to 0.050 Gm. every fifth day and after the eighth injection to 0.075 Gm. and following this general rule of increases reach an optimal dose of 20 mg. per kilogram. As soon as the interval between injections reaches seven days, a bismuth compound should be given intramuscularly, particularly bismuth salicylate. The bismuth compound should be given once a week between the sulpharsphenamine injections but never substituted for the sulpharsphenamine itself. The dose should not exceed 25 mg. of bismuth metal per week. The length of the sulpharsphenamine and bismuth course should be fifteen injections of each. The interval between sulpharsphenamine courses should be from four to six weeks, this period being covered by the administration of bismuth. A total of from thirty to thirty-five injections of each drug should be considered a minimum if the tolerance permits. Mercury injections may be used after the completion of the sulpharsphenamine and bismuth courses but should not be used during the sulpharsphenamine treatment. Mercury by mouth should be discarded.

Rest intervals not properly covered by bismuth treatment will result in relapses in the congenital syphilis of infants as in the acquired syphilis of adults. Such a child must be kept under observation throughout life and the treatment renewed if necessary. Treatment should be continued for at least a year after the total disappearance of every sign of the disease, both clinical and serologic. Spinal fluid examination should be made at the end of the second and third years.

The syphilitic infant, usually cachectic, presents difficult nutritional problems. Breast milk should be given if possible. The proper vitamins should be added to the diet. Anemia if present should be combated by iron.

BLOOD FLOW THROUGH KIDNEY

To the Editor:—After reading your answer to the question by an Alabama M.D. in regard to volume of blood flow through the kidney per minute (*THE JOURNAL*, July 14, p. 129) I see no reason why this cannot be done, because it has been done by experimental physiologists and, with certain modifications, could be applied to determining the blood flow per minute through the kidney of man. The method is to catheterize each kidney individually, i.e., each ureter, and then do a blood urea or sulphate determination on the catheterized urine specimen on a measured volume collected over a measured length of time and from this calculate the flow of blood through the kidney per unit time. In doing this test other nontreshold substances could be chosen, but sometimes others which are ordinarily nontreshold substances will exceed the threshold and no longer be nontreshold substances; but if urea or inorganic sulphate is used as the nontreshold substance, this difficulty will be overcome.

OLIVER V. RENAUD, Medical Student, Chicago.

ANSWER.—The most serious objection to the method suggested for determining blood flow through the kidney, and one which entirely invalidates it, is the fact that excretion of urine is not necessarily proportional to blood flow. This fact has been demonstrated repeatedly. Recent studies on the experimental animal, in which the flow of blood through the kidney was measured accurately by the thermo-stromuhr method of Rein, revealed a general parallelism, although not a direct proportionality, between blood flow to the kidney and creatinine clearance. Medes and Herrick (*Proc. Soc. Exper. Biol. & Med.* 31:116 [Oct.] 1933) observed that in the cases in which fluctuations in blood flow were large, and in which creatinine clearance levels failed to return to their preoperative level (with application of the unit to the renal artery), there was no direct proportionality between the blood flow and creatinine clearance. Similarly, it has been noted by Herrick, Essex and Baldes

(*Am. J. Physiol.* 99:696 [Feb.] 1932) that, in some cases of diuresis in the experimental animal, the flow of blood through the kidney did not increase.

In addition, it should be recalled that the kidney is an organ in which there is often great variation in blood flow, in arterial, glomerular and venous pressure and in secretory activity, and under the circumstances of many variable factors it is necessary that all other factors be constant or known in order to conclude that variability in one factor, for example in excretion of a substance, is directly proportional to any other single factor, such as, for example, blood flow. Similarly, there is no proof that blood flowing through the kidney is always cleared of a nontreshold substance in the same proportion and to the same extent.

From the practical standpoint, bilateral simultaneous catheterization might reflexly interfere with excretion of urine by one of the kidneys.

CORONARY THROMBOSIS AFTER SUDDEN EXERTION

To the Editor:—A white man, aged 47, married, father of several children, who has enjoyed good health all his life, having worked at hard farm labor for the past eight years, never missing a day, was suddenly taken ill in the following manner: While about his usual work loading baskets of potatoes on a truck, he slipped on a potato while in the act of raising a basketful above his head. He was suddenly seized with a severe pain in the chest, associated with nausea and vomiting. He was taken to his home, where he was seen with the usual signs and symptoms of coronary thrombosis. He was treated with rest, and morphine was required to control the pain. After several weeks' rest in bed he improved enough to be removed to a hospital, where an electrocardiogram corroborated the diagnosis of coronary thrombosis. Several days later he attempted to do light work against medical advice. The condition was aggravated, infarcts developing in both lungs and multiple emboli occurring, together with marked jaundice. Eventually the patient died. The autopsy proved the diagnosis, the cause of death being given as cardiac dilatation, coronary thrombosis, with resulting multiple emboli. The question in point is, therefore, not the diagnosis but the cause of the attack. Is it possible that in a man, heretofore symptom free, such an attack should be brought about or precipitated by sudden unusual exertion? Can you give me references to or give me a case in point where such a condition has been brought about? Please omit name.

M.D., New Jersey.

ANSWER.—One knows too little in regard to the causative factors in coronary thrombosis to say much that is definite in this case. The possibility cannot be ruled out that a thrombosis had occurred silently, prior to the exertion, and had caused a certain amount of damage. This damage did not express itself subjectively or objectively until the time of the exertion, when a damaged ventricular wall was forced to withstand an increased intraventricular pressure.

Attacks of coronary thrombosis are more frequent at rest, or in the rest following exertion, but do occur during exertion.

S. A. Levine (*Medicine* 8:245 [Sept.] 1928) reports the cases used in his study. Cases 73 and 95 occurred suddenly during exertion.

Hochrein (*München. med. Wchschr.* 81:1653 [Oct.] 1933), in an article in which he discusses the possibility of foreseeing coronary thrombosis, mentions briefly the occurrence of coronary thrombosis due to sudden psychic shock.

THE SKIN AS A SOURCE OF ANTIBODIES

To the Editor:—Is it generally considered true that most of the immunity developed in the system when bacterial invasion takes place is produced by the skin in generating antibodies or substances that act on the germs? For instance, it is well known that a severe attack of smallpox will at times clear up or apparently does clear up syphilis. If this is true, the skin must be the medium by which antibodies form, or whatever substance it is that acts antagonistic to the spirochetes. What drugs are known, if any, that will assist the skin in developing this immunity? Please omit name.

M.D., California.

ANSWER.—While the skin no doubt plays an important part in reactions of immunity, it is not an accepted teaching that the skin is the main source of antibodies. The exact place or places where antibodies are formed is not known for sure, but the evidence at hand indicates that the lymph nodes, the spleen, the marrow and the reticulo-endothelial system, which is widely distributed, are concerned directly in antibody formation. In smallpox there is no evidence that the reactions which result in immunity are limited to the skin. The so-called specific lesions may occur in the pharyngeal, esophageal and rectal mucous membranes as well as in the skin. The spleen is enlarged, the marrow may be the seat of small foci of necrosis, and there are cellular infiltrations in the liver and other organs. These lesions indicate that the virus of smallpox and its products are widely disseminated throughout the body and consequently reach antibody forming centers everywhere. If it is true that an attack of smallpox actually does "clear up" syphilis,

this effect might be due to a nonspecific stimulation of anti-syphilitic reactions like that which appears to take place in instances of nonspecific protein therapy for other conditions. It is safe to say that no drugs are known that will stimulate directly the immune reactions of the skin.

ELONGATION OF TRANSVERSE PROCESSES OF LUMBAR VERTEBRAE

To the Editor:—Please inform me as to the probable danger of strain or injury in the case of long transverse processes of the fifth lumbar vertebra that touch or practically touch the sacrum or crest of the ilium. Also inform me as to the remedy for this condition.

E. C. McCulloch, M.D., Staten Island, N. Y.

ANSWER.—Elongation of the transverse processes of the fifth lumbar vertebra is a lesion that forms the basis of considerable orthopedic discussion. It is interesting to note that the lesion may or may not be the cause of the symptoms complained of.

Roentgenograms may be deceptive; that is, they may indicate that the transverse process is touching the crest of the ilium whereas it might be an optical illusion, proved by stereoscopic films.

There are three other conditions in this region that should be considered:

1. Calcification of the iliolumbar ligaments.
2. Sacralization of the fifth lumbar transverse process.
3. Lumbarization of the first sacral segment.

It is interesting to note also that elongation of the transverse process may be on the side contralateral to the region complained of.

Many of the symptoms clear up when the area is treated for arthritic lumbosacro-iliac strain or arthritis, but some require resection of the transverse processes, for which condition Magnuson, Bauman, and Putti of Bologna, Italy, have described a successful operation.

The roentgenogram may be deceptive in indicating to the surgeon that this is an easy operation.

DERMATITIS OF EYELIDS

To the Editor:—A woman has had dermatitis of the lids for six months. During the last three weeks she has abstained from the use of cosmetics with only fair results, although this is the only improvement noted to date. How long a period of abstinence from the use of cosmetics is required for one to form an opinion of the offending agent? Please describe the patch tests as I should use them. Can witch hazel cause dermatitis of this type? The trouble in this case is limited to the lower lids and the lower edge of the upper lids. The patient had a "nervous breakdown," which kept her in bed for a month just preceding the present trouble. Could she have received anything during treatment for the breakdown internally or through the skin that could have caused this dermatitis? Please omit my name.

M.D., New York.

ANSWER.—The condition described may not necessarily be due to cosmetics but may be some other form of allergy or may be a reflex. If the offending cause is removed, the condition should clear spontaneously within a comparatively few days. It is unlikely that witch hazel can cause the condition described. The patch tests had best be made by a trained allergist, as they do not mean much to one untrained in allergic methods. It is suggested that the patient be observed to determine whether or not irritating substances are used that will continue the condition described. In the meantime the use of water and creams of any sort is to be avoided and the area should be covered each night with a simple zinc oxide ointment.

MALDESCENT OF TESTICLES

To the Editor:—The article of Dr. Samuel Cohn of San Francisco on the "Anterior Pituitary-Like Principle in the Treatment of Malescent of the Testicle" (*THE JOURNAL*, July 14) has an especial interest for me in that I have several such cases. However, two are infants aged 5 and 6 months, respectively. I should like to know whether there has been any such work on infants of this age, or would it be better to wait until school age before administering the substance? Please omit name.

M.D., New Jersey.

ANSWER.—The experience of most pediatricians indicates that many instances of malescent of the testicle, noted at birth, will show spontaneous improvement during the first few months of life. Others descend during the first few years. However, since it is the general consensus that intra-abdominal testes show a considerable tendency toward malignant changes and, since the higher temperature of the abdomen (as compared with the scrotum) is thought to tend toward testicular atrophy or at least impaired function, it would seem that the use of anterior pituitary-like substance is justified even at as early an age as 1 or 2 years. Some authors, however, believe that the hypertrophy of the accessory sexual organs incident on such therapy may be disadvantageous at this early age.

STREPTOCOCCIC IMMUNITY IN DOGS

To the Editor:—I have been told that dogs are immune to the effects of streptococci. I want to know if this is true, and I would also like to know if there has been any experimentation with dogs, goats and donkeys in the preparation of antitoxins. If you can tell me where I can get this information, I will thank you.

J. J. HANNA, M.D., Quanah, Texas.

ANSWER.—Comparatively little seems to be known about the action of streptococci in dogs. The statement is sometimes made that dogs are "relatively immune" to streptococci. Forms of streptococci occur in the intestine of dogs. According to Hamilton Kirk (Canine Distemper, London, Baillière, Tindall & Cox, 1922) "Jensen in 1896 declared that the pneumonia of distemper was due to a streptococcus which he demonstrated."

Occasional experiments have been made with dogs, goats and donkeys in the preparation of antitoxin. Foshay (*Am. J. M. Sc.* 187:235 [Feb.] 1934) has prepared a potent antitularense serum from the blood of immunized goats. The difficulty of excluding the possibility that a given dog might be in the incubation period of rabies would make it unsafe to use the dog for antitoxin production.

BRANCHIAL CYST

To the Editor:—I have under my care a full term normal male infant about 3 weeks old. At the age of 3 days a swelling was noted at the angle of the jaw on the right, anterior to the sternomastoid muscle. The swelling appeared to be subcutaneous and cystic and continued to enlarge. Aspiration was done after two weeks and 10 cc. of straw colored fluid was removed. The cyst is probably branchiogenic in origin. What treatment would you advise? If you advise a sclerosing agent, which should be employed? The maternal grandmother states that the mother had a similar condition in infancy, which disappeared spontaneously. A brother of the mother also had the same condition but died in infancy. A 2½ year old sister of this patient has a cleft palate and club feet and is feeble-minded. Please omit name.

M.D., Michigan.

ANSWER.—From the description and location, the diagnosis of branchial cyst is probably correct. The treatment of such conditions with caustic and sclerosing agents is unsatisfactory and not recommended. If the cyst is quite superficial, as seems likely, excision is not difficult and is desirable. Deeper cysts or fistulas of branchial origin require greater skill for their successful removal. Superficial cysts and fistulas of this group may eliminate themselves if an external opening is maintained. As long as the swelling does not increase there is no hazard in delay, although spontaneous cure is hardly to be expected.

POSSIBLE TUBERCULOUS ULCER OF TONGUE

To the Editor:—I have a patient who has moderately advanced pulmonary tuberculosis. There is also some slight laryngeal involvement but no ulceration that I have seen. Several months ago this man had a sharp tooth on which the tip of his tongue became cut very slightly. The tooth has been taken care of, but an ulcer has formed at the tip of the tongue where the small cut was. He had the ulcer three or four months previous to his visit to me. I am in doubt just what steps I should take in the treatment of this lesion. Should I leave it alone? Should I cauterize it? If so, with what? If left alone, what will be the ultimate outcome? Please omit name and town.

M.D., California.

ANSWER.—Because of the presence of pulmonary tuberculosis, the possibility of this ulcer being tuberculous should be seriously considered. Examination of smears made from the floor of the ulcer for the tubercle bacillus should be done, or a piece of the ulcer removed by biopsy may be examined by a pathologist for tuberculosis. If the diagnosis of tuberculosis is sustained, the lesion should be removed with the actual cautery or by excision, the wound being closed with sutures. If not removed, the tuberculous ulcer of the tongue tends to spread, becomes very painful, and in its later stages offers a serious prognosis. Removal by excision or the cautery is probably wise even though a diagnosis of tuberculosis is not made.

OPERATION FOR CATARACT

To the Editor:—Can you give me the name of an ophthalmic surgeon who does the intracapsular (Indian) operation for cataract for choice? I understand that some men do the operation in clinic cases but will not do it in their private work, which seems to me to be an indication that they do not have much confidence in it. I am developing cataract in both eyes, and the lenticular opacities are so centrally located that I will in all probability have a long period of semiblindness before I can have the usual two stage operation. If there is any one in the middle West who has had enough experience in the one stage operation to do it successfully I should like to consult him.

M.D., Ohio.

ANSWER.—The majority of ophthalmic surgeons have abandoned the Indian intracapsular operation because of the high risks involved. Those of clinical experience who perform the

intracapsular operation are utilizing the Elschmig technic, the Knapp technic or the Barraquer technic. All these methods are of the intracapsular type, all are fairly safe, and all yield satisfactory results in the hands of experienced operators. None of these types of operation require full maturity of lens as does the older intracapsular method. In practically every large city there are one or more experienced ophthalmic surgeons doing one of these intracapsular operations.

LARVAE IN HUMAN SKIN

To the Editor—I recently saw a child, aged about 6 months, who had several papules on its body from two of which, the mother claims, a white larva about half an inch in length escaped. She brought the larva to the office but it was dried and unrecognizable, although it certainly was a larva of some kind. The other papules dried up and disappeared. I have been unable to find anything in the literature regarding such skin condition.

M D, Ontario.

ANSWER.—A great many larvae of widely different forms have been found in the human skin, some of them burrowing and forming a narrow, usually crooked, inflammatory line, designated creeping eruption. Others form only a papule, which in some cases enlarges to resemble a furuncle.

Two recent articles in American literature on creeping eruption are:

Bedford, G. V., Williams, D. H., and Newton, M. V. B.: *Creeping Eruption Caused by Gastrophilus Intestinalis*, *Canad M A J* 28: 377 (April) 1933

McCarthy, Lee: *Creeping Eruption Due to Ancylostoma Brasiliense*, *Arch Dermat & Syph* 27: 490 (March) 1933

The larvae of heel flies, incorrectly called bot flies, are sometimes found in human skin, producing papules or furuncle-like lesions with a black point at the apex, an opening through which the larva breathes. This is hypodermiasis or ox warble disease (Toomey, T. N. *Brit J Dermat* 34:31 [Feb] 1922). Warble is an old word related to "wormil," meaning a swelling due to the larva of the heel fly.

ELECTROCOAGULATION IN CHRONIC ENDOCERVICITIS

To the Editor—Can one use the electrocoagulating portion of a diathermy machine in the treatment of chronic endocervicitis or is the cautery more advisable? Kindly omit name if this is answered in THE JOURNAL

M D, New York

ANSWER.—Removal or destruction of the diseased endocervix may be accomplished in many ways. The entire cervix may be cored out, or it may be coagulated with the diathermy machine. In the hands of the majority of experienced men, the nasal cautery tip has proved to be the most satisfactory. The outfit for employment of this method is now relatively inexpensive and should be included in the armamentarium of every one whose work includes the treatment of gynecologic patients.

SYPHILITIC IRITIS

To the Editor—I am writing in regard to two syphilitic iritis cases I now have under treatment. Would you please advise me of your latest methods of treatment for such cases?

GORDON LAWYER, M D., Cambridge, Ohio

ANSWER.—If the iritis is in the active stage, the best results will follow the use of foreign proteins combined with anti-syphilitic measures. Typhoid vaccine in shock-producing doses should be given intravenously every forty-eight hours for from three to six injections, to be followed immediately by nearsphenamine in small but frequently repeated doses. It is far better to use 0.1 Gm. every forty-eight hours than 0.3 Gm twice a week. In these stages, iodides are of but little value. The local treatment is the same as for any form of iritis; namely, atropine and heat. If the acute stage of the iritis has passed, it is far better that the ophthalmologist turn the patient over to a syphilologist for further treatment.

IDENTIFICATION OF SEMINAL STAINS

To the Editor—In your answer to the question of M D., Kentucky, in relation to the identification of seminal stains found in the clothing of the deceased after death (THE JOURNAL, October 20, p 1255) you state that the semen might run out through a bullet wound involving the seminal vesicles and that it is also a possibility that stains might have been deposited sometime before the episode that led to the man's death. While this is correct as far as it goes, one of the most important considerations is the postmortem ejaculation of semen that not infrequently follows many types of death, especially violent ones. The latter fact must be borne in mind if serious errors are to be avoided.

LOUIS L. LEFKOWITZ, M D., New York.

Assistant Medical Examiner.

Council on Medical Education and Hospitals

COMING EXAMINATIONS

ALABAMA: Montgomery, Jan. 7. Sec., Dr. J. N. Baker, 519 Dexter Ave., Montgomery

AMERICAN BOARD OF DERMATOLOGY AND SYPHILOLOGY: *Written (Group B candidates)*. The examination will be held in various cities throughout the country, April 29. *Oral (Group A and Group B candidates)*. New York, June 10. Sec., Dr. C. Guy Lane, 416 Marlborough St., Boston

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY: *Written (Group B candidates)*. The examination will be held in various cities of the United States and Canada, March 23. *Final oral and clinical examination (Group A and Group B candidates)*. Atlantic City, N. J., June 10-11. Group B application lists close Feb. 23 and Group A application lists close May 10. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh

AMERICAN BOARD OF OPHTHALMOLOGY. Philadelphia, June 10. *Application must be filed at least sixty days prior to date of examination*. Sec., Dr. William H. Wilder, 122 S. Michigan Blvd., Chicago.

AMERICAN BOARD OF OTOLARYNGOLOGY. New York, June 8. Sec., Dr. W. P. Wherry, 1500 Medical Arts Bldg., Omaha.

ARIZONA: *Basic Science*. Tucson, Dec. 18. Sec., Dr. Robert L. Nugent, Science Hall, University of Arizona, Tucson. *Medical*. Phoenix, Jan. 23. Sec., Dr. J. H. Patterson, 320 Security Bldg., Phoenix

COLORADO: Denver, Jan. 18. Sec., Dr. Wm. Whitridge Williams, 422 State Office Bldg., Denver.

DISTRICT OF COLUMBIA: *Basic Science*. Washington, Dec. 27-28. *Medical*. Washington, Jan. 14-15. Sec., Commission on Licensure, Dr. W. C. Fowler, 203 District Bldg., Washington.

ILLINOIS: Chicago, Jan. 22-24. Superintendent of Registration, Department of Registration and Education, Mr. Eugene R. Schwartz, Springfield

IOWA: Des Moines, Jan. 3-5. Dir., Division of Licensure and Registration, Mr. H. W. Greife, Capitol Bldg., Des Moines

MINNESOTA: *Basic Science*. Minneapolis, Jan. 23. Sec., Dr. J. Charnley McKinley, 126 Millard Hall, University of Minnesota, Minneapolis. *Medical*. Minneapolis, Jan. 15-17. Sec., Dr. E. J. Engberg, 350 St. Peter St., St. Paul

NATIONAL BOARD OF MEDICAL EXAMINERS: *Parts I and II*. The examinations will be held in medical centers where there are five or more candidates, Feb. 13-15. Ex. Sec., Mr. Everett S. Elwood, 225 S. 15th St., Philadelphia

NEBRASKA: *Basic Science*. Omaha, Jan. 8-9. Dir., Bureau of Examining Boards, Mrs. Clark Perkins, State House, Lincoln

NEW YORK: Albany, Buffalo, New York and Syracuse, Jan. 28-31. Chief, Professional Examinations Bureau, Mr. Herbert J. Hamilton, Room 315 Education Bldg., Albany

WISCONSIN: Madison, Jan. 8-10. Sec., Dr. Robert E. Flynn, 401 Main St., LaCrosse

West Virginia July Report

Dr. Arthur E. McClue, secretary, Public Health Council of West Virginia, reports the oral and written examination held in Wheeling, July 9-11, 1934. The examination covered 11 subjects and included 110 questions. An average of 80 per cent was required to pass. Fifteen candidates were examined, all of whom passed. Twelve physicians were licensed by reciprocity and 1 physician was licensed by endorsement. The following schools were represented:

Book Notices

A Text-Book of Pathology. Edited by E. T. Bell, M.D., Professor of Pathology in the University of Minnesota, Minneapolis. Second edition. Cloth. Price, \$8.50. Pp. 767, with 366 illustrations. Philadelphia: Lea & Febiger, 1934.

This edition, enlarged and revised, is an improvement, as new material has been added. The book contains sufficient pathologic physiology and clinical data to make it a more interesting and more suitable book than the older textbooks that are confined largely to the descriptive morbid anatomic and microscopic changes. The text is concise, the language is simple, the style is easy, and the sentences are noted for their short and clear cut expressions. The first portion consists of a section on general pathology, perhaps too brief, but which if supplemented by lectures would meet the purpose in the average course of study. The section on tumors can be considered adequate. A great part of the book is taken up with special pathology, which is treated in an excellent and concise manner. Illustrations are for the most part adequate. Perhaps a few statements might be questioned. Rheumatic fever is not generally accepted as yet as being due to streptococci. On the other hand, scarlet fever is most generally accepted to be due to a special type of hemolytic streptococci. In a discussion of streptococcic sore throat epidemics, a statement that the infection may be milk borne through contamination of a milk man with a sore throat is incorrect, as all work points to the infected udder of a cow being the source of infection. The term *Streptococcus mucosus* is still employed and should not be used in American literature, as this organism is definitely *Pneumococcus mucosus*. Tumors are discussed in an excellent brief manner. The relation of trauma, chronic irritation and the experimental work on production of cancer are well discussed. The histogenetic terms for tumors of the nervous system have been adopted. Lympho-epithelioma tumors of the throat are included. An interesting addition to the discussions of the tumor are the remarks on prognosis and radio-sensitivity of neoplasms. The classification of diseases of the kidney is confusing. The recent conceptions of nephrosis are emphasized. In discussing diseases of the heart, Clawson includes a simple, clear classification and emphasizes recurrent rheumatic infections of the heart, a condition neglected by most textbooks. One might perhaps question the statement that Aschoff nodules occur in 45 per cent of cases of subacute bacterial endocarditis, as most workers believe that these nodules are seen only in rheumatic infections. The pathology of only a few infectious diseases is discussed. In a discussion of hay fever, a statement that the majority of hay fever sufferers finally develop asthma is of course incorrect. The pathology of nervous diseases includes a brief statement of the various forms of encephalitis and parkinsonian diseases. The chapter on diseases of the blood is written by Downey. The histogenesis of blood cells and the recent work on liver and liver extracts in relation to the anemias are well described. Agranulocytosis is considered infectious in origin, and the possible relationship to amidopyrine is not mentioned. These omissions, however, are comparatively slight, for the book is well balanced and serves as an excellent textbook for beginners in pathology. It brings practitioners recent work and pathology discussed in terms of clinical medicine and abnormal physiology.

Active Immunization Against Diphtheria: Its Effect on the Distribution of Antitoxic Immunity and Case and Carrier Infection. By Sheldon F. Dudley, Percival M. May and Joseph A. O'Flynn. With a note by J. Orr Ewing. Medical Research Council, Special Report Series, No. 195. Paper. Price, 3s. Pp. 140, with 15 illustrations. London: His Majesty's Stationery Office, 1934.

An unusual opportunity presented itself at the Greenwich Hospital School in London to study the degree of immunity acquired under natural conditions by a group of about 1,000 boys over a period of seven years in comparison with the immunity obtained under artificial conditions of immunization at the same institution. From 1921 to 1928 the authorities at this school would not permit the administration of an immunizing agent but did sanction the Schick testing of the children. During the following five years, artificial immunization with toxoid was employed. The authors concluded that

three doses of diphtheria toxoid can produce in three months as high an immunity as three years' residence in a community where diphtheria is endemic. The community in this instance was the boys' school, where the children live rather intimately, associated with one another and subjected to the dangers of direct contact infection. The authors further state that the natural progress of immunization was accompanied by a high mortality and that there occurred one case of clinical diphtheria for every three or four latent immunizations. When active immunization with toxoid was employed in 1928, clinical diphtheria almost disappeared from the school; but in the winter of 1932 a rather virulent outbreak occurred in spite of the fact that about 90 per cent of the children were Schick immune. This outbreak was due to a diphtheria bacillus extremely toxigenic and virulent to guinea-pigs. The incidence was greater among those who had been immunized with toxoid than among the natural Schick immune. However, the cases in the Schick immune or in the relapsed Schick immune were all mild. It was observed that, after the artificial immunization of the school, higher virulent carrier rates were recorded, while the number of avirulent carriers practically disappeared. They observed, however, that in determining this variation in the percentage of virulent carriers the same boys have not been observed over an extended period of time. They believe, however, that the sampling does represent a fair index of the variation in the carrier rate. The authors confirmed the hypothesis first verified experimentally by Dudley in 1922 and Zingher in 1923 that latent immunization is caused by carrier infection with virulent diphtheria bacilli. They further state that artificial active immunization is an almost certain protection against recognizable clinical diphtheria but is no protection against carrier infection. It may under certain conditions increase the number of virulent carriers, not only by replacing the Schick susceptibles who rarely carry virulent diphtheria bacilli, by Schick immunes who are all potential carriers, but also by substituting virulent for avirulent diphtheria infections.

A Textbook of Gynecology. By Arthur Hale Curtis, M.D., Professor and Head of the Department of Obstetrics and Gynecology, Northwestern University Medical School. Second edition. Cloth. Price, \$6. Pp. 493, with 300 illustrations. Philadelphia & London: W. B. Saunders Company, 1934.

This edition contains 112 pages more than the first. Lacking is the usual publisher's statement listing revisions and additions. A detailed comparison of the second with the first volume is essential to an understanding of the conscientious way in which the new material has been woven into the original fabric. Credit is due the author for this painstaking work, nor should credit be withheld from the publisher for permitting an almost complete resetting. The orderly sequence of the original volume and its concise virtue are not lost, yet substantial progress is made toward a broader consideration of fundamentals, found wanting in the first edition. Whether through remissness or modest intent, neither author nor publisher has signalized the improvements in the second edition. Some of them should be mentioned: The section on cancer of the cervix has been revised and improved for teaching purposes. Admirable illustrations of the Wertheim hysterectomy comprise a valuable addition. A new section on tumors of the broad ligaments is included. An operation not included in the first edition is advocated and carefully described. This consists in the combination of advancement of the bladder with transfer of the bases of the broad ligaments and amputation of the cervix.

The section on internal secretions in their relation to gynecology is entirely rewritten and greatly enlarged and improved. The management of pelvic tuberculosis is seen from a slightly different angle; surgery is soft-pedaled. The sections on operative management and postoperative care have been admirably rearranged and amplified. The section on sterility is broadened and strengthened. For the rest, there is scarcely a section in the book, however brief, that has not come in for its share of change for the better.

The illustrations, for the most part by Tom Jones, offer a striking contribution to the excellence of the volume. Many illustrations of interval stages in operative procedures have been added, reduced in size without loss of subject value. In general, the illustrations of operative procedures are unusually good,

particularly those depicting plastic procedures involving the vaginal approach.

As a basic textbook for the academic teaching of gynecology, this book is not yet ideal. It is practical, concise and readable but, after all, more concerned with clinical essentials than with fundamental and academic grounding. For clinical teaching combined with case study and surgical observation it is nearly perfect. As a reference for the clinician in practice it is invaluable.

In the surgical management of prolapse, cystocele and rectocele, in the conservative and radical management of pelvic infection and in the management of genital cancer the book is superlative. In certain fields, particularly in vaginal plastic surgery, it is a classic, years ahead of its time. For the rest, it is often excellent, seldom less than adequate. The first edition proved to be an invaluable adjunct to the working library. The second edition is greatly broadened in scope and commensurately more valuable. No book in its field will be referred to more frequently or with more profit by either clinician or specialist.

Union Internationale contre le cancer; Conférence préparatoire tenue le 22 mars 1934 au Ministère de la Santé publique à Paris. Compte rendu sténographique. Paper. Pp. 80. Paris: The Union, [n. d.]

These two pamphlets are a transcript of the organization meeting of the International League Against Cancer. The first International Cancer Congress originated at the suggestion of the late Dr. Harvey R. Gaylord of the State Institute for the Study of Malignant Disease, at Buffalo. As Professor Czerny had just opened his institute for cancer investigation in Heidelberg, and Prof. Paul Ehrlich the institute for experimental therapy in Frankfurt, the meeting was held in September 1906 at Heidelberg and Frankfurt. The congress was attended by representative clinical and laboratory students of cancer. Obviously, as the meeting was held in Germany, the members were predominantly German, but representatives from England, France, the United States and other countries were present. Every aspect of the subject was considered, scientific research, treatment both by surgery and radiation, and statistics. Among the famous men present now no longer living were Jensen, Metchnikoff, Pozzi, Waldeyer, Czerny and Ehrlich. Jensen died only a few months ago, and it was he who in one sense originated experimental cancer research, for he was the first to study in detail the transplantation of animal tumors. The second congress was held in Paris in 1910 and was well attended. In 1913 another small conference was held in Brussels. Then came the war, and it was not until 1923 that a conference was held in Strasbourg, with a limited group of investigators attending. The American Society for the Control of Cancer called a conference in 1927, which was held at Lake Mohonk. In the scope of its papers this meeting was chiefly devoted to the questions of teaching, lay publicity and the organization of cancer clinics in which the society was interested. A year later a similar invitation conference was called in London, and certain phases of the cancer problem were discussed in great detail. This meeting was more general in scope than the Mohonk conference. Both conferences published important contributions to the subject of cancer research and cancer education in their proceedings. Finally, in 1933 the third international congress assembled in Madrid. The decision to hold this congress was made rather late and it was difficult to get together a representative group on short notice. It was felt by the delegates to the Madrid conference that some more formal organization should be created which would guide and somewhat control future congresses, the next of which will be held in Rome in 1936. In compliance with the wishes of the delegates to this congress, Justin Godart, president of the French Society for the Control of Cancer, was requested by the president of that congress to call a meeting of delegates from those organizations interested in cancer, and this meeting was held March 22 of this year in Paris. The response was world wide, sixty-eight delegates coming from North and South America, all the countries of Europe and some from the Far East. The purpose of this meeting was to decide whether there should be created a formal organization to be known as the International League Against Cancer. This group decided that it would be wise to establish such a body, voted that its headquarters should be in Paris, and discussed the

many activities in which such an organization might properly engage. It was recognized that a question of immediate importance was to aid the local committee having charge of the next congress in Rome and to assist it in the organization of its program of papers, clinics and symposiums and also to suggest possible subjects for discussion. To this end a constitution and by-laws were adopted which should govern further developments. All teaching and research organizations are eligible to join the society on the payment of a small fee, and governments also are asked to nominate delegates. Among other suggestions for the possible activities of the society was that to prepare an international classification for tumors and to determine uniform criteria for the recording of cancer statistics. If sufficient funds can be obtained, it was proposed to establish a central office in Paris, from which information of all sorts concerning cancer might be supplied, reprints collected to be lent to investigators unable to subscribe to the journals containing the original articles, photostats prepared at the request of investigators unable to obtain reprints, and a card index of the literature on cancer to be made so that any investigator might obtain, at a small cost, the literature on any phase of cancer research or education on which he desires information. It was also proposed to publish a small, inexpensive bulletin which would be sent to all the members of the organization and to others interested in the subject of cancer, reports of the committee meetings and of the plenary conferences of the delegates, with short notes on other matters that might be of interest to those engaged either in research or in treatment of cancer and in cancer education. An executive committee was elected by the plenary conference to carry on in the interim and it met in Paris, July 17. The full meeting of all the delegates from the various countries that have agreed to combine in this venture will be held in Paris, December 16. At that meeting it is expected that the outlines of the program for the Rome International Cancer Congress will be completed and a permanent executive committee established from those countries which have sent official delegates.

Surgical Nursing. By Hugh Cabot, M.D., C.M.G., F.A.C.S., Senior Consultant, Mayo Clinic, Rochester, Minn., and Mary Dodd Giles, R.N., A.M., Associate Professor of Nursing Education, Vanderbilt University. Second edition. Cloth. Price, \$3. Pp. 441, with 123 illustrations. Philadelphia & London: W. B. Saunders Company, 1934.

The authors have attempted to state underlying principles of the practice of surgery and to correlate surgical nursing procedures with these principles. They have been fairly successful, though the correlation might be improved. In some instances the treatment represented to be indicated is apparently quite individualistic and does not conform to the accepted principles of many surgeons. There is a tendency to encourage the nurse to take over a considerable part of what is still regarded as the practice of medicine. The illustrations might be improved in order to cause them to be of educational value and not merely illustrations. Submitting this edition to a representative group of recognized surgeons and conforming to their recommendations might result in a more practical, worth-while third edition.

Über die Wirkungen der Röntgenstrahlen auf die Lungen. Von Rolf Bull Engelstad. Acta radiologica, Supplementum XIX. Paper. Price, 10 Swedish crowns. Pp. 93, with 35 illustrations. Stockholm: P. A. Norstedt & Soner, 1934.

It has been known for many years that excessive irradiation of the chest with either radium or x-rays can produce permanent fibrotic changes in the lungs. This fact was of relatively little practical importance until the development in recent years of the method of administering extremely large doses of radiation in the attempt to cure cancer of the lung, mediastinum or breast. While Holfelder has suggested the use of an oblique beam in the treatment of carcinoma of the breast and many workers in the field supplement moderate roentgen treatments with large doses of buried but highly filtered radium the action of which is chiefly local, nevertheless it has become more and more obvious that this fibrosis of the lung is one of the limiting factors in the treatment of malignant conditions in the chest. Most of the previous work on the subject has been done in a purely qualitative way and with doses that could not be administered to human beings. This monograph is therefore a welcome contribution to the subject. First of all, Engelstad has

been careful to determine the dosage of x-rays that he administered, no matter what the filtration or voltage. He used rabbits in his experiments and protected them as far as possible with lead rubber. Small animals of this type are not suitable for such work, as the lateral scattering from the impinging beam is considerable and the animals may not infrequently die from moderate exposures. Beginning with moderate doses just sufficient to produce an erythema, approximately 1,500 roentgens, or about three times that for the human skin, he found no serious damage in the lung or pleura. The lymph follicles were shrunken and there was some hyperemia with edema of the lung tissue, and occasionally some capillary hemorrhages. The lymph follicle changes appeared in a few hours after the irradiation, the others later. Equal numbers of roentgens applied to the chest gave the same effect despite the variations in voltage and filtration. With larger doses, approximately 3,400 roentgens in a single sitting, fairly extensive degenerative processes could be observed four hours after the termination of the exposure. The lymphocytic tissue of the lung had practically vanished. Leukocytic exudate was present in the alveoli. The alveolar epithelium showed degenerative changes and after some months the lungs showed considerable sclerosis, degeneration and proliferation of the bronchial epithelium, exudate in the pleura, calcification, and even the presence of bone. To this lesion the rabbit is probably peculiarly sensitive. The dose causing these changes, however, is larger than would ever be given to a human being in a single sitting but is not larger than is at present frequently administered with the fractional technic now employed. The author found in his experiments that the time factor played an important part in determining the amount of lesion in the lung, for while no difference was noted when equal doses of x-rays of different wavelengths were administered in the same time, when the treatment was greatly prolonged a much larger total dose could be given than when the whole was administered at a single sitting, thus confirming the work of Coutard and his followers. In another series of animals, doses between 9,000 and 21,000 roentgens were given. As might be expected, most of the animals died fairly promptly even when the dose was divided into three or four sittings, but such doses would never be given to human beings. Obviously, the reader will consult the text for the histologic details and will be instructed in these matters by the excellent illustrations, mostly photomicrographs, of the damaged tissues. An extensive bibliography is appended. The subject would seem to be closed, certainly for the rabbit, and it is unlikely that the use of dogs or cats would reveal any other changes of importance.

Diabetic Manual for Patients. By Henry J. John, M.A., M.D., F.A.C.P., Director of the Diabetic Department and Laboratories of the Cleveland Clinic. Second edition. Cloth. Price, \$2. Pp. 232, with 47 illustrations. St. Louis: C. V. Mosby Company, 1934.

This manual is attractively written and will hold the attention of the patient. The diagrams are ingenious. The text is sound, sensible and practical. The author cheers the patient by recording a list of patients who took insulin and later were able to discontinue it. Many will differ radically with his interpretation of reactions and will not agree that they are present with a high blood sugar; but that is a comparatively minor point. Sample menus are given for carbohydrate 140 Gm., protein 60 Gm., fat 111 Gm., and evidently this is a diet which the author frequently employs. Any practitioner can recommend this manual to his patient without any misgivings. It is sure to do good.

Vie et rajeunissement: Une nouvelle méthode générale de traitement et mes expériences de rajeunissement de Bologne et de Paris. Par le Dr. Francesco Cavazzi. Préface du Profr. Charles Richet de l'Institut de France. Paper. Price, 22 francs. Pp. 88, with 47 illustrations. Paris: Gaston Dolin & Cie, 1934.

Dr. Cavazzi of Bologna has a method which is a variant of that of testicular extract injection. Cavazzi says that Brown-Séquard's original method of opotherapy failed, not because it was wrong in principle, but because he had used an extract that did not and could not contain the active endocrine substances. The testicular hormones (like other hormones) pass directly into the efferent blood, according to the exact conception of an internal secretion as enunciated by Claude Bernard.

The author therefore used the serum of testicular efferent blood from young and healthy animals, as this, he declares, must contain the testicular hormones. According to Cavazzi, the species of animal is a matter of indifference, because the efficacy of the hormones is a chemical matter. A number of old men were treated both at Bologna and in Paris. Cavazzi says that all were greatly improved. He believes that the phenomena of "rejuvenation" observed are due to the amelioration of the specific nutrition of the nervous system (hormone nutrition) and especially of the spinal cord by the action proper of the testicular hormone. This, he avers, is a biologic, not a pharmacologic or pharmacodynamic, excitation: a reacquisition of nervous energy by the action of the hormones. Nothing is said about the method of preparation of the serum. The clinical data given are especially meager. Empiricism is the substance of the work. It is regrettable that the term "rejuvenation" is used rather loosely. More scientific and exact data instead of speculative statements, coupled with subdued enthusiasm, might perhaps tend to less skepticism.

Physical Diagnosis. By Richard C. Cabot, M.D. Eleventh edition. Cloth. Price, \$5. Pp. 540, with 317 illustrations. Baltimore: William Wood & Company, 1934.

The new edition of this standard textbook has been thoroughly revised and reset in new type. Sections concerned with laboratory data have been omitted, thus offering more space for other chapters. Coronary heart disease is much more adequately described in this edition than heretofore. A section on pulmonary heart disease has been added. The sections on head and neck, tuberculosis, pulmonary emphysema, and lesions of the large intestine have been enlarged. A new chapter is devoted to the electrocardiogram. As the author stresses in the preface, no attempt has been made to describe diagnostic procedures with which he is not familiar and no space is given to the description of tests that he believes are useless.

A Contribution to the Problem of the Relationship Between the B Vitamins and the Protein, Fat and Carbohydrate Contents of Food. By P. Vogt-Møller, Reservelæge ved St. Elisabeth's Hospitals Medicinske Afdeling, Copenhagen. Paper. Pp. 165. Copenhagen, Denmark: Levin & Munksgaard, 1934.

This report, in Danish, accompanied by an English summary, covers experimental investigations (1929-1931) in which mice were used to ascertain whether requirements for the B vitamins vary at different levels of protein, fat and carbohydrate in the diet. This question is important in the quantitative determination of the B vitamins as well as from a clinical standpoint. When given a rich fat diet, the animals seemed to need less vitamin B₁, while the requirement of B₂ seemed to be increased; increased vitamin B₁ caused an earlier development of pellagra and death. A high carbohydrate diet seemed to increase the need for B₁ and/or B₄. A high protein diet appeared to increase B₂ needs. The results of the experiments show that the composition of the diets on which experimental animals are fed has a large influence on the quantitative biologic determinations of the constituents of the vitamin B complex, so that the feeding of experimental animals with diets of uniform composition is necessary in comparative investigations of the vitamin content of foods.

Applied Anatomy: The Construction of the Human Body Considered in Relation to Its Functions, Diseases and Injuries. By Gwilym G. Davis, M.D. Ninth edition revised by George P. Muller, M.D., Professor of Clinical Surgery, Graduate School of Medicine, University of Pennsylvania. Assisted by Bernard J. Alpers, M.D., Assistant Professor of Neurology, Graduate School of Medicine, University of Pennsylvania, Sirlin W. Moorhead, M.D., Assistant Professor of Urology, University of Pennsylvania, Robert A. Kimbrough Jr., M.D., Associate in Obstetrics and Gynecology, University of Pennsylvania, I. S. Ravidin, M.D., Professor of Surgical Research, University of Pennsylvania, and S. Dana Weeder, M.D., Surgeon to the Germantown Hospital. Cloth. Price, \$9. Pp. 717, with 675 illustrations by Ervin F. Faber. Philadelphia, London & Montreal: J. B. Lippincott Company, 1934.

The profession will welcome a revision of a book that is considered by many to be a classic. The fact that this is the ninth edition attests its popularity. It has been entirely reset and, in part, reillustrated. The author's aim was to teach surgical principles through the medium of anatomic relations. Many of the sections have been rewritten, notably the surgical specialties. A few sections have not been rewritten and an excellent example is the part on extremities, which was so well

written originally that few changes were indicated. Most of the illustrations were made from dissections made by the author, or under his direction. The frozen anatomic sections should be of considerable value to the student and surgeon. The reviser and his assistants have done a commendable piece of work. The book represents an excellent job of publishing and can be recommended highly.

Medicolegal

Medical Practice Acts: Revocation of License; Pregnancy to Be Proved When Abortion Is Charged.—The state of Iowa instituted an action in equity to revoke Brown's license to practice medicine, charging him with unprofessional and dishonorable conduct in procuring a criminal abortion. The trial court dismissed the proceedings. The state then appealed to the Supreme Court of Iowa. That court reversed the order of the trial court and directed it to revoke the defendant's license but later, on rehearing, affirmed the trial court's ruling dismissing the cause.

To establish the charge that Brown procured a criminal abortion, said the Supreme Court, the evidence must show that the female on whom the operation was alleged to have been performed was pregnant. This, the court held, the evidence in this case failed to do. The girl herself, a child 15 years old, refused to testify. The trial court did not permit her family physician to testify, because of the privileged communications statute of Iowa. Her mother testified that the family physician said the child was pregnant; but, said the Supreme Court, this testimony, while admissible as proof that the statement was made, cannot be considered as evidence of the truth of that statement. There was evidence that after the family physician had advised the mother as to the child's condition her father arranged with the defendant to treat her; that the defendant examined her and advised that she be given quinine; that the girl visited the defendant two or three times subsequently; that on one visit he used a metallic instrument and inserted a rubber tube and some gauze in the vagina, and advised the removal of the tube when the child began to have cramps; that about five hours later the child did have cramps and the tube was removed; and that the child passed clots of bad-smelling blood the following morning. This evidence, said the court, fails to show that the child was pregnant, since there was no expert evidence that these treatments were such as are recognized as adapted to and ordinarily given to produce an abortion and were not given for a legitimate purpose. There are many things in the evidence, said the court, that arouse a very strong suspicion, but the court cannot condemn on a suspicion.

Holding that the evidence failed to establish that the child was pregnant, the Supreme Court accordingly affirmed the ruling of the trial court dismissing the proceedings.—*State v. Brown (Iowa)*, 245 N. E. 348; 253 N. E. 836.

Malpractice: Volkmann's Contracture Attributed to Tight Bandage.—The plaintiff sustained a compound fracture of the humerus, about three inches above the elbow. The defendant-physician, at a hospital, reduced the fracture, placed the arm in a splint, and bandaged it. The plaintiff remained in the hospital ten days, during which period the bandage was changed two or three times. After the plaintiff left the hospital, although he complained of pain, the bandage was not changed for approximately three weeks, at which time the splint was removed. It was then discovered that the plaintiff had a Volkmann's contracture, evidenced by inability to straighten the wrist and fingers. The injury was permanent and practically deprived the plaintiff of the use of his arm from the elbow down. Charging the defendant with negligent treatment, the plaintiff sued and obtained a judgment for \$4,000, from which the defendant appealed to the Supreme Court of Washington.

The plaintiff attributed his condition to tight bandaging that stopped the flow of arterial blood. The defendant apparently contended that the permanent disability was due either to a

blood clot that got into the artery feeding the lower arm or to an injury to the spiral nerve sustained at the time of the fracture. The medical testimony was in substantial agreement that if during the three weeks immediately prior to the removal of the splint the hand was excessively swollen and had a bluish or purplish color, it would indicate that the flow of blood had been arrested by pressure on the arm. If, on the other hand, "the flow of blood was arrested by a blood clot or injury to the nerve," the hand would be pale or have a cadaverous appearance. Lay witnesses who had seen the hand and arm during the three weeks testified that the hand and fingers were excessively swollen and had a bluish or purplish color. This testimony, observed the court, directly supported the plaintiff's theory and the medical testimony offered by him to the effect that the bandages were too tight and that this caused the disability. There was testimony that if the hand, during the three weeks, became excessively swollen, or if the patient complained of pain, the bandages should have been removed to determine the cause. We recognize the rules, said the court, that the mere fact that bad results follow treatment is not of itself evidence of negligence on the part of the physician, and that if the treatment actually employed has the approval of at least a respectable minority of the medical profession there would not be negligence. These rules, however, have no application in the present case, because the question is what caused the condition of the arm. If the condition was caused by too tight bandaging, it necessarily follows that the defendant was negligent in failing to give the arm proper care. The mere fact that more physicians testified for the defendant than for the plaintiff was not considered by the court to be of controlling importance. The Supreme Court concluded that the judgment of the trial court was warranted by the evidence and that judgment was affirmed.—*Griginski v. Lane (Wash.)*, 30 P. (2d) 970.

Workmen's Compensation Acts: Landry's Paralysis Attributed to a Cold.—On March 8, 1932, a very cold day, the employee, during the course of his employment, fell into a hole filled with water, wetting one of his legs. On the following morning he went to work as usual but complained that he did not feel well. He returned home about 3:30 p. m. and went to bed. His family physician was called and prescribed for a cold. The employee returned to work the next day but continued to complain of feeling bad. Complaining of neuralgia of his face, he was compelled to quit work, March 24, and was taken to the Walter Reed Hospital on the evening of March 25. An examination disclosed that he was suffering from Landry's paralysis. He died on the morning of March 26. Under the longshoremen's and harbor workers' compensation act, made applicable to the District of Columbia by an act of Congress, the deputy commissioner awarded compensation to the employee's widow. The supreme court of the District of Columbia sustained the award and the insurance company appealed to the Court of Appeals.

The only question with which we are concerned, said the Court of Appeals, is whether there is substantial evidence of a causal connection between the immersion and the paralysis. The attending physician testified that, prior to the accident, the employee was in perfect health and that in his opinion there was a causal relation between the accident and the paralysis. This conclusion, he testified, was reached "by a process of elimination." Asked to explain this statement, the physician testified that Landry's paralysis may be due to various causes, infection, exposure to cold, infectious diseases, like typhoid fever, scarlet fever and other fevers, and tuberculosis. Every potential cause other than exposure to cold, he testified, was eliminated in the postmortem report. A physician who performed an autopsy on the body testified that "this man apparently got his cold from the submerging and Landry's paralysis from the cold. . . . There is a causal relation between the 'flu' and Landry's." There was other medical testimony but the court did not deem it necessary to consider it, because the testimony already reviewed was sufficient to sustain the award. The decree of the supreme court of the District of Columbia sustaining the award was affirmed.—*Massachusetts Bonding & Ins. Co. v. Hoage (District of Columbia)*, 69 F. (2d) 575.

Society Proceedings

COMING MEETINGS

American Academy of Orthopedic Surgeons, New York, Jan. 14-16. Dr. Philip Lewin, 104 South Michigan Boulevard, Chicago, Secretary.
American Association for the Study of Neoplastic Diseases, Dec. 27-29. Dr. Eugene R. Whitmore, 2139 Wyoming Avenue, N.W., Washington, D.C., Secretary.
Puerto Rico, Medical Association of, Santurce, Dec. 14-16. Dr. Julio R. Rolenson, Box 3403, Santurce, Secretary.
Society of American Bacteriologists, Chicago, Dec. 27-29. Dr. James M. Sherman, Cornell University, Ithaca, N. Y., Secretary.

AMERICAN ASSOCIATION FOR THE STUDY AND CONTROL OF RHEUMATIC DISEASES

Third Conference on Rheumatic Diseases

First Annual Meeting, held at Cleveland, June 11, 1934

(Continued from page 1804)

The Rôle of the Reticulo-Endothelial System in the Deposition of Colloidal and Particulate Matter in Articular Cavities

DRS. JOHN G. KUHN and H. L. WETHERFORD, Boston: The most important function of the reticulo-endothelial system is that of active phagocytosis. When the cells of this system are unable to free the body from invading micro-organisms, infection takes place; and when toxic substances or bacteria cannot be removed with sufficient rapidity, local injury of tissue results. This study attempts to ascertain the activities of the reticulo-endothelial system in and about joints. A 1 per cent solution of trypan blue was repeatedly injected, subcutaneously, into animals, chiefly rats. After many injections, some animals died without apparent cause. Extensive staining of skin, subcutaneous tissues, liver, spleen, kidneys and bone marrow was found. Moderate staining of joints was found after numerous injections, but practically none after one or only a few injections. Numerous dye-laden histiocytes were seen beneath the synovial membrane. The reactions of joint tissue to a mixture of trypan blue, sodium carminate and india ink were studied. The histologic observations suggest that absorption and deposition of particulate matter occur in proportion to the size of the individually precipitated particles. There was little evidence of intra-articular inflammatory response. Since these experiments indicate that material larger than molecular size can be carried by the mobile cells of the reticulo-endothelial system from the skin and subcutaneous tissue and stored in joints, it would seem that bacteria and metabolic products not in solution are handled similarly.

The production of a mild inflammation in articular tissues by the intra-articular injection of potassium iodide tended to increase the deposition of the subcutaneously injected trypan blue. In joints experimentally traumatized, there was no definite increase in the deposit of trypan blue in the articular tissues, although there seemed to be a much greater accumulation of dye-laden histiocytes in periarticular tissues. By repeated intra-articular injections of india ink or liquid petrolatum, attempts were made to block the reticulo-endothelial system; that is, to fill its cells so completely that further phagocytosis was impossible. With others we were unable to produce more than a temporary depression of phagocytic activity. The resulting transitory, local blocking is ineffective in preventing the deposition of colloidal and particulate matter elsewhere.

Absorption of material into joints from the gastro-intestinal tract can result by way of the cells of the reticulo-endothelial system, as demonstrated by intra-articular deposits of dye given intragastrically. After noting the unequal distribution of these materials, and their feeble phagocytosis and storage in joints in comparison to other tissues, one wonders how solutions of intricate molecular composition and the host of colloidal solutions advocated for arthritis can be very effective as bactericidal agents or metabolic stimulants.

DISCUSSION

DR. ROBERT B. OSGOOD, Boston: Drs. Kuhn and Wetherford seem to have proved that materials of greater than molecular

size can be carried to the joints from the gastro-intestinal tract and from other tissues through the medium of agents belonging to the reticulo-endothelial system. However, such possible etiologic material seems to be stored in the articulations less easily than in other tissues, for example the bone marrow. The corollary of this suggests the question, which the investigators very sanely raise, as to whether various injected substances, such as vaccines, are likely to be therapeutically effective in arthritis, considering their intricate molecular composition and the many colloidal solutions, which would seem to be probably much attenuated and perhaps actually changed in composition before they can reach the joint tissues. The paper is so thought provoking that it stimulates the hope that its authors will continue their research along these lines.

DR. JOSEPH KOVACS, New York: I hardly believe that acute inflammations in general stimulate the cells of the reticulo-endothelial system to increased activity. Under such conditions an increase in deposits of dye might be explained by the fact that, in acute inflammation, there is an increased supply, and perhaps stasis, of blood which would enable the histiocytes to absorb and store more dye from the blood. Although an impaired circulation can be found in more than half the cases of chronic arthritis, I doubt that an increased storage of dye could be found except in the more acute or subacute stages, when increased blood supply and stasis are present.

The Effect of a High Fat Diet on Four People with Gout

DRS. L. MAXWELL LOCKIE and ROGER S. HUBBARD, Buffalo: Two male patients with tophaceous gout and two with tophaceous gout were fed a diet high in fat while they were free from symptoms (at least one week after the end of their previous attack). The diets contained from 20 to 50 (generally 50) Gm. of carbohydrate, from 50 to 60 Gm. of protein and from 220 to 300 Gm. of fat; they were low in purine content, containing an average of 0.04 Gm. of uric acid daily. Each time these patients were given such a high-fat diet a typical attack of acute gouty arthritis developed within two to six days, generally within forty-eight to seventy-two hours. The joint symptoms subsided completely within two to three days after the patients were placed on a diet high in carbohydrate, such a diet consisting of from 350 to 400 Gm. of carbohydrate, from 50 to 60 Gm. of protein and from 50 to 130, although generally from 50 to 60, Gm. of fat. The uric acid in the blood of such patients on a high-fat diet increased if they were kept on the diet long enough. Simultaneously, the excretion of uric acid in urine decreased. In the case of a boy, aged 16 years, with tophaceous gout the uric acid in the blood rose from 8.6 to 16 mg. while he was on the high-fat diet, and it remained at the latter concentration for several days in spite of the institution of a diet high in carbohydrate, until salicylates were given, when it reverted to its former level. The presence of acetone in these cases was not determined, although it may be assumed that some degree of ketonuria was present. A negative effect of seven days of a high fat diet on the symptoms of several patients with atrophic or hypertrophic arthritis was observed. Since a diet high in fat did not aggravate the symptoms of patients with atrophic or hypertrophic arthritis but did provoke exacerbations among four patients with gout, it seems possible that this procedure may be a useful test in the differential diagnosis of gout. These observations also suggest that the logical diet in gout should include a low fat content.

DISCUSSION

DR. PHILIP S. HENCH, Rochester, Minn.: A few years ago I reported a study of 100 cases of gout. An outstanding fact was that it took about fifteen hundred years to diagnose them; that is, an average of fifteen years elapsed between the first attack and the establishment of the correct diagnosis. The reason for such delay lies in the erroneous idea that the characteristic changes used in the past for diagnosis are expected to appear reasonably early, and that hyperuricemia, punched-out areas and preferably tophi should be present before a diagnosis is made. Palpable or roentgenographic tophi are generally late phenomena, and even the uric acid in the blood may be normal for some time after the onset of gout. Obviously, more help is needed in making early diagnoses. Even when the physician

is certain of the diagnosis, a patient often refuses prolonged dietary restrictions unless he can be convinced that certain foods are harmful. Herein lies one of the values of provocative tests in gout, although these test diets in use today are generally of doubtful value. When the response to a high purine test is undoubtedly positive, its significance is appreciated; but, unfortunately, responses are often unconvincing, even in known gout. Less than half of a series of patients with known gout noted significant increases in symptoms, and in some the uric acid in the blood was lower just after than before the high purine test diet. In about 15 per cent of a series of cases of undoubted chronic atrophic arthritis, increases of pain were noted on the test diet; however, this probably was coincidental. The report of Drs. Lockie and Hubbard proposes a more useful provocative test and suggests a definite therapeutic corollary as well as a new line of thought concerning the pathogenesis of gout. While Harding and his colleagues spoke of the effects of a "high fat diet," both they and Umeda insisted that "a diet sufficiently high in fat to produce ketosis" was necessary to produce significant increase in the blood uric acid. The diets used by Lockie and Hubbard were probably not ketogenic, as it is practically impossible to develop ketosis on a carbohydrate intake of more than from 15 to 20 Gm. It must be determined whether ketosis is a requisite for a provocation. I have given a few patients with chronic atrophic (infectious) arthritis diets high in fat, with the carbohydrates varying between 15 and 50 Gm. No flare up of joint symptoms was noted, and no unusual rise in uric acid in the blood was noted unless ketosis was established. The therapeutic corollary is of greater importance. It may be possible for a patient with gout to enjoy less restrictions with regard to purine if he is protected by a high intake of carbohydrate. These studies indicate anew that gout is not a problem just of purines or uric acid but that it is more profound. The French have demonstrated that cholesterol is precipitated in tophi in addition to urates. This work might be interpreted as indicating in gout a disturbance of fat as well as of purine metabolism. To date, however, it is thought that fats merely lower the ability of the kidneys to excrete urates. In the meantime, with the increasing use of ketogenic diets for infections of the urinary tract, if acute arthritis suddenly develops in a patient being so treated, an investigation for gout seems in order.

DR. FRANCIS HALL, Boston: This paper calls attention to the fact that gout still exists in the United States. Erroneously calling it rheumatic fever, toxic, traumatic or hypertrophic arthritis, physicians are misdiagnosing a large number of cases of typical and atypical gout because they fail to think of it. It suggests a more accurate method of diagnosis. There are many cases of arthritis without tophi, with or without the typical series of attacks but with borderline concentrations of uric acid in the blood, and in these roentgenograms may reveal punched-out areas in bones and it may be difficult to make a diagnosis. A provocative diet high in purines is of value in some cases, but a diet high in fat may prove of greater diagnostic merit. This study emphasizes what has previously been known but not generally recalled, and that is that a high fat intake retards elimination of urates by the kidneys and that the diet in gout should be high in carbohydrates and low not only in purines but also in fat. It must also not be forgotten what Folin, Berglund and Derick demonstrated, that a diet high in purine-free proteins stimulates excretions of urate. There are many unsolved problems concerning gout and uric acid; for example: Why doesn't gout attack patients with a high concentration of uric acid in the blood, such as in nephritis, leukemia, polycythemia, and pneumonia? What part, if any, does the liver play, and why is there a diminution in the excretion of uric acid before an attack? Searching for other leads in solving these problems, I have found a low metabolic rate among some patients between attacks of gouty arthritis. They have also exhibited stigmas, a history, and a response to medication with thyroid extract suggestive of thyroid deficiency. If this is not coincidental it may indicate that a slow flow of blood may be a conditioning factor. Burian demonstrated that exercise increased the excretion of uric acid from three to five times. Trauma will precipitate gout, and I have seen several patients whose pronated feet led to trauma of the knecs and toes. Correction of such defects may be important.

Calcium and Cholesterol Metabolism in Arthritis

DR. EDWARD F. HARTUNG, New York: Previous studies on the calcium balance and concentration of calcium in the blood serum of patients with arthritis have been few and are inconclusive. By Clark's modification of the Kramer and Tisdall method I have determined the serum calcium in fifty cases of atrophic (rheumatoid) and in fifty cases of hypertrophic (osteo) arthritis, comparing the values with those of 852 control cases previously studied at the Mayo Clinic by Greene and Hench in addition to 128 controls of my own. There is a slight but significant decrease of serum calcium in hypertrophic arthritis. This decrease cannot be explained by the fact that this disorder occurs in an old-age group. The serum calcium in rheumatoid arthritis does not disclose a significant variation from normal.

It has been observed that there is a significant decrease in the blood plasma cholesterol with some infections. By the method of Sackett I have found an increase of plasma cholesterol in cases of hypertrophic arthritis. This increase cannot be explained by the fact that patients with this disorder tend to be obese. The plasma cholesterol in atrophic arthritis tends to be lower than the average normal. The arithmetical mean for cholesterol in fifty-nine cases of hypertrophic arthritis was 235 mg. per hundred cubic centimeters of blood; in thirty-three cases of atrophic arthritis it was 175 mg., compared with the mean value of 195 mg. for a control group of thirty-three normal persons. These observations suggest that hypertrophic arthritis is a degenerative disease and that atrophic arthritis may be infectious.

The Roentgenologic Changes in Various Types of Chronic Arthritis

DRS. G. D. TAYLOR, A. B. FERGUSON and HAIG KASABACH, New York: We have studied in detail the roentgenograms in fifty-two cases of rheumatoid (atrophic) arthritis, thirty-two cases of osteo-arthritis, twelve cases of gout, eleven cases of gonococcic arthritis, thirty-two cases of tuberculous arthritis, twelve cases of Marie-Strümpell spondylitis, and twelve cases of Still's disease. The six chief alterations studied were general and local decalcification, production of bone by lippling or osteophyte formation, localized loss of bone substance, alterations in joint space, fibrous or bony ankylosis, and changes in soft tissues, such as atrophy, swelling or effusion.

In all types of chronic arthritis there may occur some degree of local decalcification, bone production, narrowing of joint spaces (destruction of cartilage) or ankylosis (in osteo-arthritis this occurs in the spinal column and sacro-iliac joints only). General decalcification is frequent in cases of osteo-arthritis (in 75 per cent of cases) but it is of slight degree and is normal for that age period, whereas in rheumatoid arthritis (in 95 per cent of cases) it is marked and extensive and is not accounted for by changes due to age. Atrophic loss of substance is as common in rheumatoid arthritis (85 per cent) as it is in gout (83 per cent). The soft tissue shadows are of utmost importance in roentgenologic diagnosis of arthritis and are frequently neglected. The hands and feet are the sites of choice to show detail in generalized roentgenologic changes, especially in rheumatoid arthritis. Anteroposterior and lateral views of corresponding joints of the extremities are necessary for determining the degree of decalcification and changes in soft tissue. The roentgenograms may show little or no change in the early months of rheumatoid, osteo-arthritis or Marie-Strümpell arthritis, gout or Still's disease, but they are important at this stage in the differential diagnosis of gonococcic and tuberculous arthritis. It is essential, for a rational interpretation of roentgen shadows, that the roentgenologist know at least the duration and the severity of the joint symptoms. No single feature is diagnostic, but each group of these clinically typical cases has a basic pattern or grouping of roentgenologic changes.

Osteo-arthritis and rheumatoid arthritis appear by the roentgenogram to be distinct entities. Both osteo-arthritis and rheumatoid arthritis may occur in the same case and in the same joint, and in such cases the characteristic changes of each type can usually be demonstrated in the same roentgenograms. The cases of rheumatoid arthritis form one distinct group with constant roentgenologic changes that do not suggest a further subdivision of this group.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*), are abstracted below.

American Journal of Cancer, New York

22: 249-496 (Oct.) 1934

- *Cancer of Stomach. H. K. Gray and D. C. Balfour, with appendix by R. R. Kirklin, Rochester, Minn.—p. 249.

- Liver in Relation to Normal and Malignant Growth: Review. A. Haddow, Edinburgh, Scotland.—p. 308.
- Neoplastic Disease of Kidney of Frog, *Rana Pipiens*: II. Occurrence Metastasis. B. Lucké, Philadelphia.—p. 326.
- Comparison of Apparent End Results in Cases of Carcinoma of Mouth in Relation to Length of Follow Up. C. C. Lund, Boston.—p. 335.
- Studies in Bone Sarcoma: II. Is New Bone Formation in Osteogenic Sarcoma Result of Local Supersaturation of Tissue Fluids with Calcium? A. Brunschwig and P. H. Harmon, Chicago.—p. 342.
- Simple Adenomatous Polyp of Rectum. W. M. Shedden, Boston.—p. 347.
- Action of Radium on Tissue Cultures. F. B. Flinn, J. Victor, N. Stillman and D. MacDonald, New York.—p. 351.
- Intensities from Various Radium Packs. M. C. Reinhard and H. L. Goltz, Buffalo.—p. 359.
- Roffo's Test in Cancer: Statistical Results of Eleven Thousand Cases. A. Gandolfo, Buenos Aires, Argentina.—p. 363.
- Tumors of Muscle. C. F. Geschickter, Baltimore.—p. 378.

Cancer of Stomach.—Gray and Balfour point out that, in its various forms, cancer of the stomach may be considered either one of the most hopeless or one of the most curable types of cancer. The increase in the incidence of malignant processes of the stomach is undoubtedly partially the result of those achievements in preventive medicine which have increased the span of life. Because of progress in diagnosis, cancer of the stomach is being recognized in its earlier stages, and on this depends the possibility of cure. Experience has now shown that a malignant process of the stomach may be curable if diagnosed early enough in its growth. Permanent cures are rare in relation to the number of cases encountered. If, however, the fact that early removal is the only known method of cure were emphasized more, a larger number of persons would undoubtedly submit promptly to examination and operation, with consequent increase in the number of satisfactory results. In cancer of the stomach, death will inevitably occur within a period of months if the disease is not interrupted in its course. The authors feel that exploration is warranted in any case of cancer of the stomach, unless it is clearly incurable because of distant metastasis or unless the lesion itself is definitely inoperable, as evidenced by roentgenologic examination.

Arsenical Keratoses and Carcinomas.—Franseen and Taylor report nine cases of carcinoma due definitely to arsenic and five cases of carcinoma probably of arsenical origin. One case in which only keratoses were caused by arsenic is described. Four additional cases, illustrative of lesions produced possibly by arsenic, are discussed. They state that arsenic may become deposited in the skin and manifest its carcinogenic property as late as forty years after the ingestion of, or occupational exposure to, arsenic. The carcinogenic property of inorganic arsenic is not universally appreciated and, as a result, cases of carcinoma of the skin may be produced inadvertently. Inorganic trivalent arsenic, usually in the form of solution of potassium arsenite, appears to be the chief offending agent. Chronic arsenical lesions following the administration of organic arsenic compounds are exceedingly rare. That arsenical carcinomas are not invariably of the squamous cell type is evidenced by the fact that more than one third of the carcinomas in the series were of the basal cell type. Although the grade of the malignant process in the squamous cell lesions is usually

low, metastasis to the groin and the axilla is not an infrequent event, as the authors attested in their series by this occurrence in nine lesions, two thirds of which were graded I, histologically. With all lesions of any considerable size, therefore, the regional lymph nodes should be removed, in spite of a low histologic grading. Patients presenting early arsenical lesions may be spared extensive operations or untimely death by prophylactic destruction of precancerous arsenical keratoses; or, by careful and frequent observation, these keratoses may be destroyed at the moment malignant changes threaten.

American Journal of Pathology, Boston

10: 569-712 (Sept.) 1934

- Formation of Intercellular Substance by Administration of Ascorbic Acid (Vitamin C) in Experimental Scorbutus. V. Menkin, S. B. Wolbach and Miriam F. Menkin, Boston.—p. 569.

- *Unidentified Parasite in Heart Muscle. W. C. Von Glahn, New York.—p. 647.
- Tuberculosis of the Major Bronchi. H. S. Reichle and T. T. Frost, Cleveland.—p. 651.

Inclusions in Renal Epithelial Cells Following Use of Bismuth Preparations.—Pappenheimer and Maechling found refractile globules within nuclei and cytoplasm of renal epithelial cells in two cases following intramuscular injection, in one instance of bismocymol (a bismuth derivative of camphocarbonic acid) and in the other of potassium bismuth tartrate with butyn. Similar globules were found in the renal epithelial cells of rats after the injection of appropriate doses of bismocymol. The chemical nature of these globules was not determined; they gave equivocal reactions for bismuth, were insoluble in lipid solvents and in strong alkalis and acids, resisted tryptic digestion and did not react for iron or calcium, but stained as myelin by the Spielmeyer method.

Unidentified Parasite in Heart Muscle.—During the routine study of the muscle of the heart from a case of aortic stenosis and insufficiency, Von Glahn discovered, at necropsy, peculiar solid bodies within the sarcoplasm of the hypertrophied heart muscle. The end of the body adjacent to the nucleus was rounded bluntly; the other end was pointed. Near the bluntly rounded end was an oval vesicular nucleus containing one or more chromatin particles, and close to this nucleus, in some instances, a solid round structure. One or more oval vacuoles were present, often near the pointed end. The bodies averaged 52.5 microns in length and 5.5 microns in width. They were usually straight, except for slight undulation. One body was found that was turned abruptly at right angles close to the muscle nucleus; another was sharply bent on itself. Another of these bodies was divided longitudinally through part of its length. Two larger bodies were discovered that had been cut across in sectioning the block of muscle. In many of the muscle fibers, fragments were found; and it was obvious that they were parts of more than one of these bodies. The only internal structure that could be distinguished, aside from vacuoles and nucleus with its nucleolus and chromatin material, were fine granules in the bluntly rounded portion. In the phosphotungstic acid hematoxylin preparations, the peripheries of the bodies were refractive. These bodies were not encapsulated; they seemed somewhat rigid in the fixed preparation. They appeared to be surrounded by clear fluid. They were situated adjacent to the muscle nucleus, with the long axis parallel to the direction of the myofibrils. The nucleus of the muscle was indented or invaginated by the bodies. The myofibrils were pushed to either side by the bodies but were otherwise unchanged. The heart muscle containing these bodies was not enlarged. There was no inflammatory reaction about the muscle containing the bodies. The bodies were numerous in the posterior part of the left ventricle and less in the muscle from the apex of this ventricle. The author has shown preparations of the bodies to many pathologists and

protozoologists. The consensus was that these bodies were of parasitic nature, but none could identify them. It is not believed that the bodies had any part in the production of the hypertrophy of the heart.

 Juvenile Paretic Neurosyphilis Studies: I. Incidence, Sex and Age at Onset. W. C. Menninger, Topeka, Kan.—p. 486.
 *Forced Spinal Drainage in Treatment of Case of Gastric Crisis. R. M. Fellows, Topeka, Kan.—p. 505.
 Diagnosis and Treatment File for Neurosyphilis Clinics. S. H. Epstein, Boston.—p. 516.

Reinfection in Syphilis and Chancre Redux.—Klauder and Butterworth present the diagnostic features of recurrent indurations of the penis and a clinically indisputable case of reinfection with syphilis. They also report a case of chancre redux associated with active neurosyphilis. Two rabbits inoculated with tissue from the chancre redux failed to present evidence of syphilis. As far as they know, this is the first reported instance of rabbit inoculation with tissue from a chancre redux. The negative results in two rabbits are inconsistent with the conception of reactivation of spirochetes at the site of the chancre. Allergy or the hypersensitive state of syphilized tissue may play a part in the development of a chancre redux. It is possible that trauma, a nonspecific irritant, acts as a stimulant to this tissue, causing it to react in a characteristic manner in the absence of the specific irritant, *Spirochaeta pallida*. The authors interpret the negative rabbit inoculation in their case as favoring the latter theory.

Forced Spinal Drainage in Gastric Crisis.—Fellows discusses a case of dementia paralytica with tabes with gastric crisis treated by forced spinal drainage. It is a therapeutic axiom to treat a case of dementia paralytica with tabes at the start as if the case were one of dementia paralytica, the tabetic element being neglected temporarily since, unless treated properly, the patient will die of dementia paralytica before he is incapacitated by the tabes. In the author's case, however, because of the distressing and damaging gastric condition, it was imperative that the treatment be pointed toward relief of a symptom that is associated with the tabetic part of the picture. The treatment was outlined as nearly as possible to conform with accepted modern methods of treatment for dementia paralytica with tabes complicated with gastric crisis; that is, intensified routine treatment with large doses of arsenicals, shorter courses of bismuth compounds and iodides, later tryparsamide, and, in case of failure, fever therapy. These measures failed to relieve the gastric crisis, and spinal drainage was instituted with beneficial results, after which malarial therapy was used. Complete alleviation of the gastric crisis with no recurrence to date followed the use of forced spinal drainage. The patient at present is working efficiently at his job, his whole attitude is changed, he is happy, cheerful and cooperative, his memory is excellent and there is no impairment of calculation. His weight, which was 171 pounds (77.7 Kg.) when he was first examined at the clinic, fell subsequently to 156 pounds (71 Kg.), but is at present 175 pounds (79.5 Kg.).

Transplantation of Living Grafts of Thyroid and Parathyroid.—Stone and his associates have made preliminary reports of their efforts to transplant living thyroid and parathyroid tissue from one animal to another. They now report further progress, describe their technic, record the beginning of a number of human experiments and prove that, at least in dogs, it is possible to have homografts of thyroid tissue live for long periods. They have employed their method of grafting in ten human cases, five thyroid and five parathyroid. Only two of these cases have been done long enough to form a basis for any conclusion as to the success of the graft. Four of the five thyroid cases were not exactly of the sort that they would recommend for testing the method. Three of these cases were infantile or juvenile patients diagnosed as cretins and in such patients there is always the possibility of pluriglandular disorders that may blur the picture and confuse inferences. The fourth was an adult with spontaneous myxedema complicated by angina pectoris, introducing a disturbing element again in the clinical estimation of the results. Only the fifth case is one of surgical removal of thyroid tissue with resultant hypothyroidism, suitable for an uncomplicated test of the procedure of grafting. In three of the five parathyroid cases, less than two months have elapsed since grafting. In the other two cases, now fifteen months and ten months respectively have elapsed since the first grafts, and the authors believe these to be successful. Their clinical recovery from all symptoms and the return of their blood chemistry to normal are evidence of such a result. The long period of stationary or progressive tetany, in spite of other forms of treatment before the grafting and the change in the picture afterward, convinces them that the grafts played a part in the recovery. It may be that they did not survive themselves but set in motion processes that led to the development of the patient's own surviving parathyroid tissue, if any was present.

Relation of Hypophysis, Hypothalamus and Autonomic Nervous System to Carbohydrate Metabolism.—Davis says that hyperglycemia and glycosuria are not produced by pancreatectomy in cats that have a lesion of the hypophysis. Bilateral hypothalamic lesions, symmetrically placed, may be followed by pancreatectomy without the development of hyperglycemia and glycosuria. Such lesions must be situated in the tuber cinereum slightly rostradorsolateral to the mamillary bodies at the level of the ventromedial hypothalamic nucleus. Stimulation of the superior cervical sympathetic ganglion and the stellate ganglion in cats produces a marked hyperglycemia and glycosuria. These results are not obtained following section of the splanchnic nerves or bilateral symmetrical lesions of the hypothalamus. There are many clinical examples of the relationship between the various lobes of the hypophysis and a neural mechanism in the hypothalamus. Besides the question of carbohydrate metabolism there is the occurrence of diabetes insipidus, adiposity, thermal regulation, pathologic sleep and states of hypoglycemia. To the influence on carbohydrate metabolism of this rather well defined neurohypophyseal mechanism is added the relationship of the autonomic nervous system and the thoracic and abdominal viscera. The author has no evidence as yet that would lead to any information regarding the source of the carbohydrates mobilized in his experiments. The work of Griffith led him to believe that hyperglycemia may develop from stimulation experiments without involving the pancreas, thyroid, parathyroid or hypophysis, provided the suprarenals are intact. As a corollary, Houssay, Biasotti and Rietti have reported that the diabetogenic action of anterior lobe extract may be observed in the absence of the pancreas, hypophysis, thyroid, ovaries, testicles, splanchnic nerves, lumbar sympathetic chains, suprarenals or a lesion of the tuber cinereum. They concluded, however, that the liver alone was necessary. Certain it is that there is evidence enough to throw some doubt on the idea that the islets of the pancreas have an independent secretory control over carbohydrate metabolism. It is well established that typical lesions exclusively characteristic of diabetes have not been found in the pancreas. In fact, Allen has observed changes in the pancreas described as characteristic of diabetes in almost 50 per cent of cases in which there was no diabetes. It would indeed be strange if nature had concentrated the control of such a vital function in one organ. It is more logical to believe that sugar disposal is more carefully safeguarded by perhaps multiple mechanisms.

Simultaneous Vein Ligation.—From their experimental studies Brooks and Johnson are convinced that ligation of veins does under certain conditions influence favorably the incidence of gangrene after arterial obstruction. In clinical experience it has been found that the most convincing evidence for assigning any value to therapeutic ligation of a vein has been found in the instances in which the conditions corresponded best with those present in the experimental laboratory. Furthermore, these instances occur infrequently. From both experimental study and clinical experience the authors believe that ligation of the vein is a measure from which beneficial results can be expected only if there is a more or less abrupt and localized arterial occlusion which reduces the blood flow in an extremity to a dangerous level for a period of time only slightly in excess of that in which the anemia would be tolerated, and if there is reason to believe that, if the gangrene can be averted for this period, subsequent development of collateral circulation will take the extremity out of the danger zone. In their clinical experience they performed deliberate ligation of a healthy vein seventeen times. In two instances in which there was localized arterial obstruction with active progress of gangrene, it seemed that the immediate and marked improvement could hardly be attributed to anything other than the venous occlusion. In fourteen instances of arterial obstruction due to arteriosclerosis, the results obtained were such as to suggest a possible beneficial effect in some instances, but they believe that one can expect a favorable result in only a relatively small proportion of carefully selected patients. They know of no evidence which would indicate that any beneficial results could be expected from therapeutic vein ligation in thrombo-angiitis obliterans.

Experimental Elephantiasis in Animals.—Homans and his associates state that experimental elephantiasis in the canine is identical for all practical purposes with the commonest

varieties in human beings: filarial, surgical, sporadic and familial. It is called forth in a typical form by lymph stasis alone and, without other influences, progresses to an advanced state of fibrosis and deformity. In the experimental and human diseases, the same high protein concentration occurs in the tissue fluid. As this concentration rises toward that of blood serum, fibrosis also increases and aggravates lymph stasis, so that a vicious circle of protein concentration and fibrosis is set up. Once elephantiasis is established there may set in the same recurrent attacks of fever and local inflammation, usually spoken of as lymphangitis. Hemolytic streptococci can be cultivated from the tissue fluids in the early hours of each attack only in the dog. The same bacteria call forth a typical attack in another animal when injected, in appropriate quantity, into a lymph-obstructed leg. It must be supposed that bacteria of a similar nature may be recovered from the tissues in human elephantiasis. The lymphatics draining the affected part, being disabled or destroyed, the tissue fluids circulate under the influence of gravity. In the dog, once the disease is well advanced, they gravitate through wide spaces lined with endothelium, which may lie close to or actually in the skin and on reaching normal tissues are carried off promptly. In the human being there is evidence that the same thing occurs. It should be the prime object of treatment, after study, with the aid of dyes, of the routes most available for the tissue fluids, to preserve at operation the greatest possible amount of tissue carrying such routes and to remove the greatest possible amount of lymph-choked fibrosed subcutaneous tissue and aponeurosis incapable of carrying the fluid. It is unlikely that the muscles play more than an indirect part in favoring the circulation of tissue fluid. Nevertheless, if the fluid could be introduced among them, this would be an advantage. There is evidence that lymphatic obstruction within the abdomen may often be a cause for elephantiasis nostra. Elephantiasis consequent on repeated attacks of infection from such sources as epidermophytosis or ulcers is probably distinguishable clinically from elephantiasis due primarily to lymph stasis. In the former, the enlargement cannot develop without the infectious attacks. In the latter, the infectious attacks are often grafted on lymph stasis and aggravate the disease.

Organic Foreign Bodies in Bronchi: Reaction of Lung Tissue in Rabbits. H. J. Hara, Los Angeles.—p. 549.

Specific Treatment in Streptococcal Infections.—The preliminary studies of Baum suggest that blood serums from patients convalescing from various streptococcal infections frequently contain immune substances antagonistic to similar but not necessarily identical organisms. Specificity seems to be indicated by positive agglutination tests. Moderate doses of such serums, properly checked for specificity, or blood transfusions from their donors, have proved highly effective in the treatment of many varieties of streptococcal infection. The method is essentially clinical, and the author has made no effort to identify the various strains of streptococci by complicated laboratory methods. Startling improvement is invariably noted in the second twenty-four hours if the serum is to be of any value to the recipient. In acute cases some improvement may even begin to show itself before that time, but seldom in less than twelve hours. There is a fall in temperature, with subsidence of swelling and soreness in the soft tissues; and diminution in discharge, if any is present. If positive and

definite improvement is not noted, it is useless to continue the administration of the serum. The author has thus far used the method with success in streptococcic tonsillitis, tonsilloadenitis, pharyngitis, laryngitis, cellulitis, otitis media, mastoiditis, sinusitis and cardio-arthritis disease.

*Rôle of Histamine in Inflammation. J. R. E. Morgan, Toronto.—p. 516.

Specific Chemotherapy for Cancer.—Eggers studied the effects of various agents on transplantable rat tumors. The two tumors used for the experiments were of rather high virulence. Of the two, strain R39 was decidedly of greater malignancy than strain FRC; it withstood implantation with almost complete success and was of rapid growth, killing its host generally within about seven weeks. Strain FRC also withstood implantation well, but not with the same uniform success. It was of slower growth and took considerably longer to cause death. Several lead salts were found to cause complete disappearance of all the FRC tumors treated; with strain R39 the best achievement was the disappearance of 50 per cent of the small number of tumors studied. Results obtained with lead salts gave no clue as to the effectiveness of the arsonium compounds. Of the several arsonium salts studied, success was obtained only with tetramethylarsonium gluconate. It was possible to cause the disappearance of relatively nonmalignant tumors in the rats studied with some, but not absolute, regularity. With more malignant tumors this effect was occasionally manifest if the tumors were treated while still small. Greater uniformity of success was obtained with these tumors, if small, when the arsonium salt was administered along with insulin. This procedure was uniformly more successful with the R39 tumor than with the FRC strain, confirming the theory on which the coadministration of insulin was based. If the affinity of a cancer cell for carbohydrate is a function of its malignancy, or vice versa, with less malignant tumors less ability of the cancerous tissue to avail itself of systemic reserve carbohydrate and so less chance of a shielding effect by this might be expected. With strain R39, particularly, the only tumors treated with any uniformity of success were those which had been implanted a short time (three days) previously. The toxicity of tetramethylarsonium gluconate for rats is low. While occasionally animals died in a comparatively short time after receiving a 5 mg. dose, these deaths occurred so seldom that they must be regarded as due to intercurrent disease. The intoxication observed after this dose was acute and apparently associated entirely with disintegration of the tumor. When the gluconate was given in doses of 5 mg. on successive days, several animals received from 40 to 45 mg. without evidence of intoxication. Only one animal was observed with changes of tissue indicative of death from intoxication which had received 20 mg. of the arsonium gluconate along with 0.08 unit of insulin. In general, the course of the treated tumors was preceded by a period of definite softening, with gradual absorption of the softened mass. At times there was direct shrinkage with increased induration; recurrences were more likely to occur after this than after softening. Indirect evidence to the effect that treatment was responsible for the disappearance is furnished by the peculiar course of the latter—the rather prompt softening, followed by gradual absorption. Also the relatively high rates of disappearance in the suitably treated rats were altogether disproportionate to those in animals treated otherwise. As to tumors in man, it would appear necessary to select cases of early and superficially accessible recurrent malignant growth; late and otherwise hopeless cases would be useless, in view of the quantitative relation shown so clearly with rat tumors. For the same reason, should the agent show any effectiveness with tumors in man, its use would appear to be as an adjunct to surgical removal of the great mass of the tumor tissue.

Histamine in Inflammation.—Morgan shows that histamine, when acting on the minute vessels of the skin of dog and man, causes capillary dilatation and engorgement with a slowing of the blood stream and an exudation of fluid. Injury and destruction of tissue, irrespective of the etiologic factor, will allow the liberation of small quantities of the amine, resulting in this reaction. The part played by histamine in the process of inflammation is confined to its effect on the small vessels. Histamine does not call forth the cellular elements in the inflammatory exudate.

Amidopyrine and Granulocytopenia.—Herz points out that the increase in the prevalence of granulocytopenia closely parallels the increase in the use of amidopyrine. The dangerous character of amidopyrine being established beyond any reasonable doubt, it should be strictly banned by the medical profession. When anodynes or antipyretics are indicated, acetanilid is a safe drug, which should be given in therapeutic doses, best combined with caffeine and potassium citrate. An alternative but less efficient drug would be acetphenetidin. By using the safer antipyretics, there is no doubt that greater efficiency will be obtained and granulocytopenia and other toxic phenomena now known to be caused by the dangerous pyrazolon group of drugs (amidopyrine and antipyrine) will be eliminated.

Effect of Dinitrophenol on Blood Cholesterol.—Grant and Schube administered alpha dinitrophenol to thirteen adult men of normal weight. The patients were given 5 grains (0.3 Gm.) of alpha dinitrophenol by mouth, daily, for a period of twenty days. The weight and blood cholesterol estimations were obtained before, during and after the administration of the chemical compound. The method of estimation of blood cholesterol was that devised by Schube. In three subjects after the administration of the alpha dinitrophenol there were definite gains of 5, 12 and 7 pounds (2.3, 5.5 and 3.2 Kg.), respectively. The largest definite loss of weight was 4 pounds (2 Kg.) in each of two subjects. In the remainder of the

cases, although the weight fluctuated in some instances, it remained essentially at its original level. The blood cholesterol in each of these cases, irrespective of alterations in the weight, showed a deviation from normal. This deviation was usually in a positive direction. The range of this deviation was not the same for all cases. In some the blood cholesterol, after a preliminary rise, dropped below "normal" before stabilizing itself within its original range. The largest positive change was 155 mg. and the smallest 13 mg. Of the group, four showed an increase in blood cholesterol of 100 mg. or more, seven had values of from 33 to 100 mg., and two had values of 33 mg. or less. The largest rise occurred on the first day in five cases, on the third day in four cases and on the thirteenth day in three cases. The largest negative change was -82 mg. and the smallest was -3 mg. The largest negative values occurred on the sixth day in four cases, on the thirteenth day in one case and on the twentieth day in five cases. The largest average positive change was 66 mg. and the largest average negative change was -38 mg.

The Reducing Substance of the Anterior Hypophysis.—Salter and his co-workers describe a method for quantitating the reducing power of the tissue of the anterior lobe of the hypophysis. Active reduction may be produced by extracts devoid of hemoglobin. The reducing substance tends to remain with the globulin fraction, which usually also contains the growth-promoting hormone, but the two do not appear to run parallel. Extracts containing the growth, thyrotropic, suprarenalotropic and maturity hormones, respectively, supplied by Collip, contained no more than traces of reducing substance. The method used for studying the activity of various preparations was based on Ahlgren's technic. The procedure consisted in determining the time required to bleach a standard amount of methylene blue contained in an evacuated Thunberg tube under arbitrarily selected conditions.

Inoculation with Heat-Killed Tubercle Bacilli.—Goodwin and Schwenker inoculated intramuscularly seventy-three infants with heat-killed virulent human tubercle bacilli. In the inoculated group of fifty children observed for more than one year there was one death from tuberculosis. The tuberculin test becomes positive in from three to thirteen weeks after the injection. Demonstrable allergy developed in seventy-two of the seventy-three children inoculated. When the tuberculin reaction is beginning to become positive, the maximal response to the Mantoux test is observed at the end of twenty-four hours. Some days later the typical tuberculin reaction appears. In nine cases sterile cold abscesses developed at the site of inoculation. Lymphadenitis occurred rarely and the abscesses all healed, leaving small depressed scars. The authors believe that the inoculated children received some degree of protection from tuberculosis and that the method is a hopeful one and that it is much less open to criticism than the injection of attenuated living organisms. The use of the vaccine should not be widespread until many more children are inoculated under the most careful supervision.

Scarlet Fever Immunization by Nasal Route.—Friedman and his associates instilled toxin into the nasal passages

in the immunization against scarlet fever in two groups of children aged from 3 to 17 years. The attempt was completely successful in 60 per cent and 71 per cent of the children, respectively, and partial immunity was conferred in a considerable proportion of the rest of the group. The inoculation was not attended by any serious local or constitutional effects. The authors maintain that active immunization against scarlet fever should be practiced as widely as is diphtheria immunization. Until the prevailing method of immunization has been so modified as to eliminate unpleasant and severe reactions and the necessity for a large number of hypodermic injections, they recommend the intranasal instillation of toxin. This method is clean, painless and free from serious local and constitutional untoward effects and has proved successful in a considerable number of cases. The percentage of successful inoculations can be definitely enhanced by the administration of a sixth and even a seventh weekly instillation in those still positive at the conclusion of the fifth inoculation. For children less than 3 years of age they recommend, provisionally, a total of 115,000, and in those more than 3,202,000 skin test doses.

Lyzed Gonococci in Treatment of Gonococcal Cervicovaginitis.—Blatt and his associates used an antigen in the treatment of gonococcal cervicovaginitis that was prepared by the induction of complete lysis of gonococci in young broth cultures through specific bacteriophage action. This product seemed distinctly less toxic than the older broth cultures that were permitted spontaneously to autolyze partially. The clinical results with the product seemed definitely more favorable than those obtained by any previous biochemical treatment that they have used. The bacteriophage lyzed gonococcus antigen did not produce disagreeable local or general reactions. Nine of eleven patients treated have remained clinically and bacteriologically cured for an average period of five months, while a control group not so treated had recurrences in every instance.

Lumbar Ganglionectomy and Ramisectomy.—Pfeiffer describes a retroperitoneal operative approach to the lumbar sympathetics, based on its use in thirty-three cases. The procedure offers a fairly direct route to the sympathetic trunk on either side of the lumbar spine, is comparatively simple and

enables a firm reconstruction during closure. Severance of the terminal nerve fibers along the outer border of the rectus on either side has not been followed by paralysis of the rectus muscles in the regions supplied. The procedure has been developed and modified from various sources, including previously described retroperitoneal approaches to the ureters. The use of a subarachnoid block associated with a moderate Trendelenburg position and tilting of the pelvis has been found to aid greatly in the procedure of lumbar sympathetic ganglionectomy, ramisection and trunk resection.

Processing Roentgenograms at High Temperatures.—

Farthing stresses the point that the temperature in processing does not have to be low, but that it must be constant. All baths, including wash water, should be within a few degrees of the same temperature. Sodium sulphate preserves the emulsion only so long as it is in contact with it, the action being purely a temporary physicochemical one. Formaldehyde, the perfect hardener, cannot be used before or during development on account of the tendency to produce chemical fog. It cannot be added to an acid fixing bath, as it causes a heavy white precipitate. When a neutral fixing bath is employed, an acid short stop must be placed between the fixing bath and the developer, or yellow stains will appear on the film. If they do occur, the film should be left in the short stop longer, the short stop should be renewed or more acetic acid should be added. Formaldehyde evaporates; so, if proper hardening does not take place, more formaldehyde should be added to the fixing bath or the entire bath should be renewed. Generalized brownish yellow stains on the films may be caused by iron salts in

the water with which the solutions are prepared or by iron dissolved out from the cracks in the enamel of trays, regardless of the developing solutions employed. This iron staining tends to occur a little more readily at higher temperatures. Formaldehyde possesses a pungent odor and is rather irritating to the mucous membranes but it is not considered harmful. If it is used in tanks, the odor is hardly noticeable.

Roentgen Sign for Saccular Aneurysm of Aorta.—Excluding the dissecting, true, false and circoid, Burvill-Holmes classes all aneurysms as saccular. Fusiform dynamic dilations often associated with marked tortuosity are not fusiform aneurysms. In virtually all cases a dorsoventral roentgenogram of the chest rarely misses the diagnosis, with the exception of those aneurysms which involve the proximal ascending or distal descending branches or in the rare cases in which the aneurysms are so small and so situated that they could be and are overlooked by any method of examination. For further refinements in diagnosis, in order to determine which portion of the branch or branches is involved, roentgenograms are made in the right and left anterior oblique and sagittal projections. The latter are imperative if any erosion of the vertebrae is to be detected, such being usually the case when the sac is large and projects dorsad. Deviation of the esophagus, while not always present, is usual, but similar displacement can and often does occur. To determine this displacement it is the author's custom to administer a thick barium-buttermilk paste. Aneurysms almost always cast a markedly dense, homogeneous shadow. In contradistinction, fusiform dynamic dilations cast a shadow much less dense because the laminated clot is absent. In all aneurysms except those mentioned previously there is always a definite angulation between the outer limit of the sac wall and the left border of the heart. This angulation is not present in cases of tumor and the border of the heart can be traced from its apex to the aortic arch. The author does not wish to convey the idea that this angle will be present in every case or that, if present, it is infallible for a diagnosis of aneurysm. There are exceptions to all rules. It is conceivable that a large upper mediastinal tumor could extend outward and downward on the left side, obscuring the left border of the cardiac shadow, and that its upper border might form an angle with the latter. An error, if it is made, will lie largely in mistaking a new growth for an aneurysm rather than the reverse.

Recuperation of Human Skin After Irradiation.—Duffy and his associates studied tissue recuperation by determining the quantity of radiation necessary to produce equal skin reactions in single and divided doses of 200 kilovolts of x-rays filtered by 0.5 mm. of copper and 2 mm. of aluminum, the threshold erythema being used as a standard reaction for comparison. The threshold erythema dose for single exposures was determined by sixty-five tests. The amount of radiation delivered to these patients varied from 400 to 550 roentgens. Of the fourteen patients who received 500 roentgens, 72 per cent showed a positive skin reaction. The incidence of positive reactions was the same for the seven patients who received 525 roentgens but was increased to 94 per cent in the seventeen patients who received 550 roentgens. Therefore, since a threshold erythema dose represents an amount of radiation that will produce a positive skin reaction in 80 per cent of persons receiving the exposure, this dose must be between 500 and 550 roentgens when administered in the manner described. Five hundred and twenty-five roentgens may be considered within the limits of experimental error of the threshold erythema dose for single exposures of radiation. In determining the threshold erythema dose for divided doses, two exposures of equal amounts of radiation were given at intervals of twenty-four and forty-eight hours. Of the thirty-five tests to determine the threshold erythema dose for two exposures of equal amounts of radiation given forty-eight hours apart, fourteen patients received two exposures of 400 roentgens each, and 72 per cent of these showed positive skin reactions. Among the eight patients to whom 425 roentgens were delivered twice, 88 per cent were positive, and the nine patients who received two exposures of 450 roentgens developed a visible reaction in the irradiated skin. Little difference was found in the amount of radiation required to produce a threshold erythema by two equal doses given twenty-four hours apart and those given at an interval of forty-eight hours.

Specific Serums Against Streptococci.—Loewenthal shows that strains of hemolytic streptococci may exhibit different forms of colonies, which differ widely in their serologic reactions. The N form is highly specific, as shown by agglutination with absorbed antiserum and by protection tests with mice. The protective value of antiserum therefore is limited to the homologous form. There are two less specific O forms; one is capsulated. Its agglutination, precipitation and capsular swelling reactions correspond to the carbohydrate nature of its capsular substance. Preparation of highly efficient antiserum is possible. All the capsulated forms seem to belong to one serologic type. The other one, the noncapsulated O form, is more frequent. Agglutination as well as protection tests indicate that there are several serologic types among this form. Cross protection can be obtained between organisms of the same type. Both O and N forms can be virulent and both forms may occur in the primary culture from disease. The prospect of successful serum therapy against the O form seems promising. The author explains the difference in mode of action of serums against capsulated and noncapsulated forms in that the antibodies of serums against capsulated strains attack the bacteria themselves and render them harmless by neutralization of their capsules, the antibodies of serums against noncapsulated streptococci cannot fulfil any such function and their mode of action can only be guessed. The serum has to be given to animals some twenty-four hours before the infecting dose. This period may be required for its thorough distribution throughout the body and its effect may be due to some protective action on the body cells and against the bacterial toxins. The protection test with mice is not a true index of the therapeutic value of these serums. Serums that have only a prophylactic effect in mice, which succumb rapidly, may show a definite curative effect in human septicemia.

Elementary Bodies of Zoster and Their Serologic Relation to Varicella.—The results of the investigations of Amies substantiate clearly Paschen's contention that elementary bodies occur in zoster vesicle fluid. It has been shown further that pure suspensions of these bodies are agglutinated specifically by zoster convalescent serums. The lack of a susceptible laboratory animal has made it impossible to employ other methods, such as high speed centrifugation of virus filtrates or the tissue culture technic, by means of which the etiologic importance of the vaccinia elementary body has been confirmed. The evidence here presented does at least suggest that the zoster elementary body is the etiologic agent of zoster. With regard to the relation of zoster and varicella, it is evident that cross agglutination tests have not given such uniform results as those obtained with the complement fixation technic. In spite, however, of the low proportion of successful cross agglutination tests, the author believes that the high degree of specificity of the reaction permits one to attach significance to the positive results obtained. The experiments carried out in his laboratory with suspensions of variola and vaccinia bodies and the corresponding antisera showed an almost complete

lack of cross agglutination (Amies, 1932). Further work on this question has shown, however, that the differences noted are quantitative rather than qualitative, since monkeys hyperimmunized with human variola virus do eventually develop antivaccinal agglutinins and, conversely, hyperimmune antivaccinal serums obtained from rabbits will agglutinate variola elementary body suspensions. The failure to obtain cross agglutination in some of the present series of experiments may perhaps be explained in the same manner. Craigie has demonstrated that crude suspensions of vaccinia virus contain a non-particulate Seitz-filtrable substance in addition to the vaccinia elementary bodies, and that it is this soluble antigen that is responsible for the vaccinia flocculation (precipitin) reaction. This substance is apparently a product of the elementary bodies themselves and is probably essentially the same as the heat stable precipitating substance isolated from autolysates of neurovaccinia rabbit testicle by Wilson Smith. It seems not unlikely that a similar nonparticulate substance may be present in zoster and varicella vesicle fluid and that complement fixation reactions with such fluids depend more on the soluble substance than on the presence of the intact bodies themselves.

British Medical Journal, London

2: 665-706 (Oct. 13) 1934

Achlorhydria.—Hurst states that without gastritis there is no achlorhydria but that gastritis does not cause achlorhydria unless the patient is predisposed by having the hyposthenic gastric constitution. Gastritis in the presence of the hypersthenic gastric constitution may lead to duodenal ulcer and gastric ulcer, and a gastric ulcer may become malignant, but achlorhydria does not develop. It is the conjunction of the apparently trivial causes of gastritis with the hyposthenic gastric constitution which leads to achlorhydria, and the conjunction of these with the constitutional predisposition to cancer which leads to carcinoma of the stomach. It is gastritis which causes achlorhydria, and gastritis, not achlorhydria, which causes Addison's anemia and subacute combined degeneration of the cord and predisposes to carcinoma of the stomach. The prophylaxis of gastritis is the prophylaxis of these diseases. One may therefore look forward to the time when the prevention of gastritis, and, when prevention fails, its early recognition and adequate treatment, will lead to the disappearance of cancer of the stomach.

Pathology and Treatment of Sprains.—Smart summarizes as follows the effects of the treatment of injured muscles and joints by correct electrical muscle stimulation, which produces graduated and controlled contractions and relaxation: 1. Muscle elasticity, irritability, contractility and tonicity are restored rapidly to normal. 2. A great increase of blood to the muscles and to the neighboring tissues is produced, with all the attendant beneficial consequences. 3. Waste tissue products are rapidly cleared away and stagnation of lymph, with all its serious sequelae, is prevented. 4. A large supply of oxygen and nourishment is brought to the damaged part. 5. Rapid absorption of fluid and extravasated blood is promoted actively. 6. Beneficial chemical and physical changes following muscle activity take place. 7. The movements of muscles and tendons do not allow organization of lymph between their surfaces, and adhesions are thus prevented. 8. As the movements prevent stagnation of lymph in the areolar tissue in the joint interspaces, the danger of the areolar tissue losing its suppleness, pliability and flexibility is diminished. 9. If, in later stages, adhesions have formed, the adherent surfaces are gently but effectively torn apart, by causing increasingly powerful contractions of the muscles separately. 10. Muscles are prevented from losing their tone and from wasting; muscles already wasted increase in bulk. A recently injured and painful muscle can still be made to contract and relax and the degree of the contractions and relaxations can be so controlled that the origin and insertion of the muscle need not be approximated until desired; conse-

quently, the beneficial physiologic changes called into activity by muscle action are produced with the minimal amount of strain of its fibers, and the movements of the injured joint as a whole can be kept within minimal range. If treatment is based on these principles, no uncomplicated acute sprain should become a chronic one.

*Chemistry of Malarial Serum, with Reference to Factors Concerned in Melanoprecipitation Test. E. D. W. Greig, E. B. Hendry and C. E. van Rooyen.—p. 289.

Pathology and Complications of Ascariasis. R. Girges.—p. 296.

Chemistry of Malarial Serum and Melanoprecipitation Test.—The experiments of Greig and his co-workers, designed to find the cause of the reaction and the nature of the precipitated material, show that when normal serum is incubated in various dilutions with distilled water a white gelatinous precipitate appears in the majority of cases. This is probably the same as the flocculation that occurs in Henry's reaction. The reaction has no obvious relationship to the concentrations of albumin, total globulin, cholesterol or chloride ion in the serum. Evidence has been given that the precipitate consists of one of the globulin fractions, probably euglobulin, and that the main factor in the reaction is the precipitation of this particular protein, owing to its occurrence in excessive amount in malaria. There are almost certainly other factors concerned. The theory that the increase in euglobulin is the main factor is supported by the observations of Lloyd and Paul that the euglobulin is increased in serums from cases of malaria or kala-azar. Melanin may be replaced by a variety of other colored substances, but it has the advantage of giving a sharp reaction and thus enables the reading of the titer to be made without any difficulty. Its use is therefore still advocated for the reaction. The melanin acts only as an indicator and the active principles in the so-called antigen are the concentration of sodium chloride and the pH . These are the factors that prevent the precipitate coming down even with a normal serum and therefore confine the reaction to those serums in which there is a far greater tendency toward precipitation; i. e., in malaria and in kala-azar. It has been confirmed that the reaction is positive in kala-azar, a condition in which the euglobulin is known to be elevated. However, since the euglobulin is also high in syphilis, in which Henry's reaction is negative, the phenomenon cannot be explained on the grounds of an increase in euglobulin alone. It is suggested that protein-lipoid complexes may enter into the question.

Trigonal Loop Traction in Suprapubic Prostatectomy.

—Lumb has evolved a technic of suprapubic prostatectomy that overcomes successfully the difficulty encountered in placing Harris's posterior suture and ensures a firm hold pending union between the edges of the trigon and urethra and can be carried out in every case. A flap of trigonal tissue is drawn down into the prostatic cavity and retained in position by means of a silk traction-loop traversing the urethra. Healing takes place quickly by granulation and the objective of the Harris operation is achieved without the uncertainty occasioned by a suture that may fail to hold.

The Leprosy Situation in England. R. G. Cochrane.—p. 306.

Spinal Analgesia with Percaine. W. H. Jones.—p. 307.

Clinical Value of Mantoux Test in Childhood.—Gaisford describes the method of performing the Mantoux test and advocates its much more extensive use among children on the grounds that it is simple to perform and yields results which, intelligently interpreted, are in many cases truer than either clinical examination or roentgenograms. He states that at some time or other during the preschool or school period of almost any child's life some signs or symptoms suggestive of tuberculous disease or infection may be encountered. Then the simple and efficacious Mantoux test is of the greatest value, particularly in its ability to exclude definitely the presence of tuberculosis in any given case. Despite the improvement in nutrition and hygiene, tuberculosis is still a common disease in childhood and is often extremely difficult to diagnose clinically. The Mantoux test is particularly applicable in chronic cervical adenitis, chronic coughs, chronic diarrhea, loss of weight and limping. The foregoing are but a few of the conditions in which the test is found to be valuable. In the majority of cases it is the negative reaction that is stressed, but in infants and young children the positive may be just as valuable.

Clinical Interest in Tuberculosis Dispensary: Cases. H. M. Williams.—p. 17.

*Relation Between Sanatorium Facilities and Total Death Rate from Tuberculosis in Canada. Madge Thurlow Macklin.—p. 22.

Induced Deposition of Calcium in Lung Tissue.—Hunter and Bell describe a gelatin acriflavine medium the injection of which is free from toxic or deleterious effects in animals. It appears that a hyaline change is an essential and preliminary stage in the process of calcification in lung tissue. A hyaline change, calcification and fibrosis can be induced in a short time by the local action of the medium in the pleural and pulmonary tissues. These processes are effected by intrapleural or intrapulmonary injections. The intrapulmonary injection of this medium is a comparatively safe procedure in the guinea-pig and rabbit, even in high dosage. The action of the medium is limited to the area injected and to its immediate neighborhood. The fact that in their experiments they have not succeeded in prolonging life the authors explain is not material in assessing results, because of the acuteness of the tuberculous process in these animals. As a result of their work they cannot but believe that the application of this intrapulmonary treatment to man would be of marked benefit in combating chronic pulmonary tuberculosis.

Death Rate from Tuberculosis in Canada.—The study of Macklin shows that there is a definite relation between the total death rate from tuberculosis in any community and its sanatorium accommodation. The communities with the greater hospital facilities for caring for tuberculous patients are the ones with the lowest death rates. Although other factors, such as climate and the susceptibility of the population, are shown to have a definite effect on the tuberculosis death rate, the main factor in lowering it is the degree to which the tuberculous patients can be removed from the community. Sanatoriums prevent the spread of infection through lowering the chances of contact between healthy and infected persons. The fact that Quebec has lowered its female death rate much less than have some of the other provinces is probably due not only

to lessened sanatorium treatment but to the larger families which the women of Quebec have. The advisability of continuing the upkeep of the sanatorium has been questioned. This study leads to the conclusion that the expense is justifiable, since it pays dividends in general public health.

Genesis of Leukopenia in Typhoid.—Hashimoto, wishing to ascertain that although thermolabile extracellular toxin (refined toxin) is weaker in pathogenic action than thermostable endotoxin (nucleoprotein) and that it acts more effectively on the blood picture, separated the two toxins by following Yato's method. These he injected into rabbits. He observed that a slight pathologic change took place only in the bone marrow, which seemed to be the sole proof of the cause of leukopenia. He next put the blood and leukocytes of the rabbits into test tubes and added the toxins to them so that they came in direct contact with the blood or leukocytes, examined the leukocidin by means of vital staining and the bioscopic method, and discovered that refined toxin contained far more poisonous matter than nucleoprotein. He thus ascertained the fact that typhoid toxin, especially refined toxin, acts directly on the leukocytes in the circulating blood and causes them to degenerate and die. This, he believes, has a bearing on leukopenia as well as the incomplete function of the bone marrow, which has been considered to be the sole cause of leukopenia in typhoid.

- Vestibular Disorders and Intracranial Hypertension.**—Barré discusses the vestibular reactions of thirty patients personally observed. Spontaneous subjective or objective vestibular disturbances (vertigo, difficult equilibration, spontaneous nystagmus and so on) were observed in fourteen of the thirty. These signs can often give a false lead to attempted localization of the causative tumor. With the cold caloric test the most frequent reaction was hyperexcitability, next normal excitability and finally hypo-excitability. In general the increased reflex action belongs especially to the intracranial hypertensions of recent origin and hypo-excitability to the old hypertensions. In the cases in which hypo-excitability to the warm caloric test was found there was almost always a similar hypo-excitability to cold. This parallelism, which does not occur in some other vestibular disorders, may therefore have some practical value. Rotatory nystagmus was of normal duration in more than two thirds of the patients. It was rarely increased and more rarely diminished in duration. Electrical excitability remained normal or nearly so in all instances. It thus seems to the author that the caloric excitability is often due to the intracranial hypertension alone, and these tests are hence often of little value in localizing the causative tumor.

Respiratory Therapy in Pulmonary Tuberculosis.—Hofbauer says that the predisposition to tuberculous infection is greatest in portions of the lung hardly at all utilized during ordinary breathing. Exclusive mouth breathing results in a loss of tonus of the excluded respiratory muscles, the diaphragm and the muscles of the abdominal wall. In case of greater respiratory requirements, respiration changes in that the auxiliary expiratory forces, the muscles of the abdominal walls, become active and in turn stimulate the diaphragm to improved inspiratory movements. The author discusses the effects of these respiratory movements and shows their value in the treatment of tuberculosis by improving the circulation. He reproduces roentgenograms that illustrate how exudates disappear following several weeks of systematic respiratory exercises. This process of resorption is important because every tuberculous focus contains a large amount of autotuberculin and work dyspnea leads to an increased resorption of these toxic products, a process that can be compared to a tuberculin injection. That the gradually increasing resorption of this substance may exert a therapeutic influence can hardly be doubted, for the production of antibodies is stimulated by the resorption. It is essential that the respiratory autotuberculinization is increased only gradually and with careful observation of the reactions. The author considers respiratory treatment of patients with pulmonary tuberculosis advisable when, as is so frequently the case, there exists an emphysema in the nontuberculous portions of the lung. Patients who have received operative treatment on account of pulmonary tuberculosis frequently develop hyperextension of the "healthy" lung and displacement of the heart. These manifestations are caused by incorrect respiratory activities, and suitable changes in the respiration will improve the condition. The method of the respiratory therapy must be individualized, but in all cases the respiratory passages should be protected as much as possible. The author stresses the exclusive use of the nose for inspiration as well as for expiration, while speaking should be curtailed as much as possible. The second important point is the training in "respiratory unburdening." The patient must learn to inhale as little as possible but to exhale as much as possible by utilizing the expiratory muscles. In unilateral involvement of the pulmonary apex or hilus and in the presence of pleural exudates or of indurations, the respiratory action of the diaphragm must be stimulated by putting the patient in certain positions. Slight changes, which at first appear to be indurations, occasionally disappear following the postural and respiratory exercises. The toxic symptoms of tuberculosis—fever, sweating, lack of appetite and loss of weight—are favorably influenced by the respiratory therapy.

Resorption and Elimination of Arsenic.—Leibowitz states that arsenic intoxications are frequently not recognized during life because of the similarity of their symptoms to other disturbances. But even the necropsy does not always bring clarity, because the typical changes in the large organs are convincing only if the examination is made shortly after death, and even then the changes may be mistaken for those of cholera or of certain meat poisonings. However, there remains the reliable chemical analysis. But in forensic medicine the question of the mode of poisoning may have to be answered. The differentiation of acute arsenic poisoning with a large dose that causes death within a comparatively short time and chronic poisoning is generally easy. Only a separate examination of the different organs is necessary. In acute arsenic poisoning (with the exception of the rare cerebral, paralytic form) death follows quickly because of destruction of tissues in the gastro-intestinal tract and before large quantities of the arsenic have reached the blood stream and other organs. In the case of slow poisoning, however, certain organs act as depots for the arsenic, particularly the hair, the long tubular bones and the central nervous system. The author reviews the various studies on the storage and the

elimination of arsenic in chronic poisoning and then describes experiments on rabbits carried out by himself and a collaborator. He found that the organism of the rabbit eliminates the largest amount of the arsenic soon after its intake. His collaborator observed that rabbits which died several days after the administration of the last of several doses showed a similar distribution of arsenic in the internal organs, as did rabbits that died after a single large dose. The only exception was the arsenic content of the pelt. Doses administered at long intervals did not result in a cumulation of arsenic in the organism; however, when two doses were given at short intervals there was a cumulation. The author thinks that the latter observation can be explained on the basis of the rapid elimination of the largest amount of arsenic soon after its intake.

Alcohol Therapy in Nontuberculous Suppurations of Lung.—Grasso found that, when intravenous injections of alcohol were administered in large doses to healthy animals exposed to pulmonary complications through artificially produced anatomic conditions (simple tracheal fistula and tracheal fistula with introduction of micro-organisms into the bronchial tree), they were able to prevent such complications. Treatment was insufficient when, because of the tracheo-esophageal fistula, the pulmonary infection was more serious and involved. The author cites four cases presenting gangrenous pulmonary abscess in which daily intravenous injections of 2 cc. of a 33 per cent solution of alcohol were administered. No favorable results were obtained. The injections did not succeed in checking the progressive course of the disease or in influencing the expectoration and temperature. The stimulating action of this treatment on the cardiovascular tonus and the general condition of the patient should be studied also from the point of view of the pneumotropic properties of the alcohol and of its pronounced lymphagogue action. This mechanism of action is confirmed by experiences reported by the author in which thorium dioxide sol introduced into the bronchial tree and absorbed by the lung and not fixed in the reticulo-endothelial system of this organ disappeared rapidly in animals subjected to alcohol therapy. To explain this the author presupposes a more active blood and lymphatic circulation in the lungs of the animals treated. The secretory functions of the alveolar epithelium are stimulated, as proved by the fact that no trace of thorium was found in the parenchymatous organs and that a true absorption of this substance with passage into the circulation is thereby prevented. The author concludes that his negative results are not sufficient to disprove the efficacy of alcohol therapy in pulmonary diseases, if administered in the early stages and in strong doses.

Bilirubinemia in Syphilology.—De Gregorio and Lopez Valiente say that an early diagnosis of hepatic insufficiency during arsenical treatment in syphilis is of importance in the prevention and the indications for treatment of arsenical jaundice, which may end in the development of acute atrophy of the liver. The authors, wishing to ascertain whether or not the changes in bilirubinemia run parallel to the intensification of arsenical treatment, made determinations of the bilirubinemia in a group of patients in various stages of syphilis. In one subgroup there was hyperbilirubinemia before the treatment, which fell to normal figures of bilirubinemia afterward. In the other subgroup there was normal bilirubinemia before the treatment, which changed to hyperbilirubinemia after the treat-

ment and returned to normal figures after the discontinuation of treatment. The results in the first subgroup seem to indicate that hepatic insufficiency and jaundice were due to the existence of hepatic syphilis, which was favorably modified by the treatment. Those in the second subgroup seem to indicate a toxic action of arsphenamine on the liver. The authors, however, were unable to give an exact interpretation to their results because of the lack of a fixed figure for normal bilirubinemia. They call attention to the advisability of establishing a figure for normal bilirubinemia that can be taken as a basis for the estimation of the liver function and changes of which should be interpreted as indicating liver insufficiency. They cite the advisability of ascertaining whether or not bilirubinemia increases in relation to the intensification of arsenical treatment and, if this is the case, what the figure is of the limit of tolerance of the organism to the drug which precedes the onset of arsenical jaundice. By fixing the limit of bilirubinemia, the development of arsenical jaundice could be prevented by the timely suppression of the drug as soon as the figures of bilirubinemia reach a warning value. In cases in which the variations of bilirubinemia point to syphilitic origin of the hepatic insufficiency and jaundice, the continuation of the treatment is indicated.

Acid-Base Equilibrium in Pregnancy.—Botella Llusia studied the acid-base equilibrium in normal pregnancy and in some of its toxicoses (hyperemesis of pregnancy, preeclampsia, eclampsia and other toxicoses). There is a slight but compensated acidosis in normal pregnancy, a noticeable although compensated acidosis in hyperemesis of pregnancy, preeclampsia and hemorrhagic toxemia, and a marked decompensated acidosis in eclampsia. In all cases the content of fixed acids in the blood and body fluids is increased and the alkali reserve is diminished. The differences are quantitative rather than qualitative. The organism tends to compensate the increased production of fixed acids. When it fails to neutralize them, actual acidosis develops, which gradually increases from figures observed in normal pregnancy to those which produce more or less grave toxicosis and even eclampsia.

 Results of Low Protein Diet Continued for Twenty-Five Months B. Süsskind—p. 195

Results of Treatment of Gastric and Duodenal Ulcers.—Frölich compares the dietetic treatment and the treatment with the jejunal tube. He reaches the conclusion that the latter produces immediate relief and in especially selected, severe cases its early results are not unfavorable as is the case with the usual dietetic treatment. In gastric ulcers the treatment by the jejunal tube is superior to the dietetic treatment. Its effects are less favorable only in some types of duodenal ulcers, in kissing ulcers and in ulcers located directly behind the pylorus. It surpasses the dietetic treatment in the reliability of its action particularly in refractory and chronic ulcers and in ulcers developing in older persons. Up to about three and a half years, the after effects of the jejunal tube treatment are superior to those of the dietetic measures. The permanent results after the latter were favorable only in one third of the cases, while in the cases treated with the jejunal tube the permanent results were favorable in nearly one half of the total number. However, neither of the two methods promises favorable results beyond the fourth year. Factors such as the constitution and the age of the patient, the duration of the ulcer and its periodicity may influence the result of the treatment either favorably or unfavorably.

Examination for Peristalsis and Antiperistalsis.—Burger states that after many years of trial he succeeded in detecting the peristaltic and antiperistaltic movements by means of a simple method, which he designates as the "beat-touch" method. He places the middle finger of the left hand on the organ (stomach or intestine) that is to be examined and with the middle finger of the right hand he percusses while advancing slowly. In observations on the stomach he found that, when he began percussion on the upper part of the fundus, the peristaltic wave returns after six seconds as an antiperistaltic wave and also spreads farther to the pyloric antrum and again returns in the antiperistaltic form. The same applies to the waves that advance from the pyloric antrum to the pylorus. These waves return in the antiperistaltic form after six seconds. Thus it is possible to differentiate from fundus to pylorus four sections of peristalsis and antiperistalsis. At the pylorus, to which the wave movements of the stomach are transmitted, the peristalsis and antiperistalsis require twelve seconds. In addition to these longitudinal waves there exist (corresponding to the transverse muscle fibers) transverse wave movements that advance from the small toward the large curvature. These peristaltic movements likewise require six seconds for their antiperistaltic return. Then there are the peristaltic movements of the oblique fibers. The longitudinal folds on the small curvature (so-called Waldeyer's stomach route) as a rule cannot be felt on the normal, empty stomach. However, they may be felt in certain abnormal conditions, particularly in hyperacidity and in ulcer on the small curvature. The author further describes observations with his beat-touch method on the duodenum, the jejunum and the colon, and asserts that the peristaltic and antiperistaltic movements of the haustra can likewise be detected with his method. In the conclusion he emphasizes that his beat-touch method is valuable in the detection of gastric and duodenal ulcers, since the wave movements are abolished at the site of the ulcer. The same applies also to carcinoma and to gastroduodenal hemorrhages.

Cerebral Embolism Following Pneumothorax and Oleothorax.—Renner gives the clinical histories of two patients, one of whom was treated with pneumothorax and one with oleothorax. Both patients died and the necropsies revealed that in the first one death was caused by cerebral hemorrhage resulting from an air embolus and in the second one by a fat embolus in the brain. In addition to these two fatal cases that were observed in more than 10,000 pneumothorax fillings, three cases were found in which similar complications developed, but these three did not terminate fatally.

Gas Diffusion in Artificial Pneumothorax.—Von Frisch and Schneiderbauer point out that, on the basis of numerous investigations on the composition of the pneumothorax gases, it may now be assumed that, independent of the type of the gas or the gas mixtures that are introduced, a constant ratio of the various gases is established in the pleural space. Di Pietro, one of the first students of this problem, found that the gas mixture consisted of approximately 6 per cent oxygen, 5 per cent carbon dioxide and 89 per cent nitrogen. The authors investigated the processes of gas exchange in artificial pneumothorax by means of metabolic studies. They reasoned that, if oxygen is used for the filling of a pneumothorax, the oxygen will be used for the maintenance of the necessary oxidation processes of the organism, in that the oxygen either enters into the alveolar air by diffusion or becomes resorbed by the tissues of the parietal pleura. If this assumption is correct, a reduction in the absorp-

tion of oxygen from the inspired air ought to be demonstrable following insufflation of oxygen into the pleural cavity. The authors determined the basal metabolism, then introduced oxygen and after that tested the basal metabolism once more. Experiments were made also with carbon dioxide, nitrogen and hydrogen. On the basis of gas analytic studies on patients with pneumothorax and on animals, the authors reach the following conclusions: After insufflation of air or of oxygen, the basal metabolism is not changed, but, after carbon dioxide insufflation, the average increase in the basal metabolic rate is 30 per cent. Inhalation of pure oxygen as well as of an oxygen-carbon dioxide mixture results in a concentration of those two gases in the pneumothorax gas. This concentration is lacking, however, in case of induration of the pulmonary pleura. In case of inhalation of a gas mixture of 70 per cent hydrogen and 30 per cent oxygen, the passage of hydrogen into the pleural cavity can be demonstrated. The demonstration of the passage of gases from the pneumothorax into the alveolar air failed in human subjects, apparently on account of the great attenuation. In animal experiments, however, it was possible to demonstrate the diffusion of hydrogen from the pneumothorax into the alveolar air. Comparative studies on dogs, in which pneumothorax or pneumoperitoneum was induced by means of nitrogen, oxygen and carbon dioxide, showed essential differences in the rapidity of resorption and of contradiffusion.

Sedimentation Speed in Pulmonary Tuberculosis.—Thiele reports the results of the sedimentation tests on 5,145 patients with tuberculosis that required treatment. It was found that among the patients with cirrhotic tuberculosis 85 per cent had a normal sedimentation speed, and among those with cirrhotic-productive tuberculosis, 68.3 per cent. The incidence of a normal sedimentation speed among the patients with productive tuberculosis was 42.3 per cent, and among those with cirrhotic cavernous tuberculosis, 47 per cent. In all other forms of tuberculosis the sedimentation speed was more or less accelerated. Of those with open tuberculosis, 25 per cent had a normal sedimentation speed. The treatment in the sanatorium produced a decrease to normal values of sedimentation only in a rather small percentage of patients. In 600 patients with all forms of tuberculosis the relation between the sedimentation speed and the outcome of the disease process was investigated. These observations covered a period of two years and three months. It was found that the sedimentation speed of the erythrocytes was closely related to the prognosis. Of the patients with a sedimentation speed of more than 51 mm. (one hour), 75 per cent died within twenty-seven months; of those with a sedimentation speed between 21 and 30 mm., 20 per cent, and of those whose sedimentation speed varied between 11 and 20 mm., 16 per cent. The tuberculosis took a favorable course in those patients in whom the sedimentation speed went back to normal values. This factor was of especial significance for the surgical treatment. Nearly all patients whose sedimentation speed decreased to normal values following surgical treatment were cured.

Tuberculosis and Age.—Kalbfleisch asserts that the primary infection of the lung predominates in nurslings, while the intestinal primary infection is still of small importance but becomes more prominent in older children. The glandular component of the primary lesion, that is, the involvement of the lymphatic glands, is characteristic for the tuberculosis of childhood. During the age of puberty the incidence of tuberculosis increases greatly. The forms of tuberculosis that develop during this period of life approach more closely the phthisis of adults, that form in which a cavern develops in the apical region, particularly in the posterior third, and which is characterized by

bronchogenic, lymphogenic and hematogenic metastases in the lung. However, the main symptom is the predominance of productive processes and the slight involvement of the thoracic lymph nodes. The endogenic lymphoglandular reinfection (Ghon) occurs in persons at the end of puberty, but even more frequently during later periods of life. Generalized tuberculosis is not frequent in adults and in the aged but it occurs occasionally and is usually a sequel of chronic cavernous pulmonary phthisis. In senile persons it generally assumes the form of miliary tuberculosis or of serous tuberculosis. The involvement of the larynx is somewhat less frequent in the aged than in younger persons, but involvement of the intestine has approximately the same incidence in the two groups. The author emphasizes the great importance of protecting the nursing against tuberculosis by removing him from a tuberculous environment or by removing persons with tuberculosis from the environment of the nursing. He states that especial attention should be given to the grandparents, whose tuberculous infection may be overlooked, but presents nevertheless a source of danger for the nursing.

Foam Thrombosis in Genesis of Cerebral Malacia and Angina Pectoris.—Löffler shows that, in severe atherosclerosis of the cerebral arteries, arterioles and capillaries, the lumen of these vessels is generally dilated while the walls are rather rigid. If the blood pressure decreases suddenly (blood pressure fluctuations in hypertension), the insufficient regulatory capacity of these vessels results in a liberation of gas from the arterial blood, and a mixture of gas and blood obstructs the capillaries. This process, which is designated foam thrombosis or foam embolism, is the cause of symmetrical areas of softening in the brain. It is assumed that, in atherosclerosis of the coronary arteries, foam thrombosis and foam embolism are the cause of the attacks of angina pectoris.

*Dietetic and Medicinal Treatment of Exogenic Obesity. G. Arany.—p. 1363.

Treatment of Exudative Pericarditis.—Hitzengerber points out that the evacuation of a chronic pericarditic exudate by means of puncture involves considerable danger, in that the rapid change in pressure disturbs the cardiac function and may result in complete failure of the heart action. In acute pericarditis there is no such danger, for in acute cases large exudates have been evacuated without resulting in cardiac complications. When he decided to treat a chronic pericardial exudate by the daily withdrawal of small quantities, the author discovered that even a chronic exudate may be evacuated without danger. The patient under treatment tolerated well a withdrawal of about 40 cc. of the exudate. On the next day it was found that the pericardial exudate had become much smaller, but in addition to it there now existed a pleural exudate. The pleura had been punctured and a communication had been established between the pericardium and the pleural space. The exudate was aspirated from the pleural space and three weeks later the pericardial exudate was completely removed by another pericardial puncture. The discharge of the pericardial exudate into the pleural space proved successful in two other cases, and on the basis of these observations the author recommends the puncture of the pericardium through the pleura (from the back). After the pericardial exudate has reached the pleural space it becomes absorbed or may be removed by puncture. There is no danger of pleurisy. Before resorting to pleural drainage of the pericardial exudate, it should be determined by a test puncture whether the exudate is free from pus, to avoid production of an empyema in the pleura.

Treatment of Exogenic Obesity.—Arany stresses three points: (1) the limitation of the intake of calories by restriction of the diet, (2) the increase in the oxidation by greater muscular activity and (3) the regulation of the water exchange by promoting the diuresis. In addition to limiting the calory

intake to from 20 to 30 per cent below the requirements computed on the basis of the body weight, the metabolic rate and the mode of life, it is necessary to restrict the intake of proteins and substitute foods of low caloric values and with much roughage. Increased oxidation is obtained by more muscular exertion, but the increase should be gradual and circulation, heart and lungs should be watched. If the muscular action cannot be adequately increased, medication with a phosphoric acid preparation may be resorted to. Since obesity is usually accompanied by water retention, a correction of the water exchange is necessary. This is accomplished by limitation of the fluid intake, by hydrotherapeutic measures, such as sweat cures, and by increasing the diuresis. The author increased the diuresis by intragluteal injections of a mercury preparation at intervals of from three to four days. The total number of injections was from three to four. Constipation, which exists occasionally, should be counteracted by mild purgatives. Carlsbad salt is helpful, because it also increases the diuresis.

Anaerobic Strains of Diphtheria Bacilli in "Malignant Diphtheria."—Kollath calls attention to the fact that it is still unknown why even the largest doses of serum do not effect a cure in malignant diphtheria. He thinks that the failure of the antitoxin indicates a component the nature of which is as yet unknown, and he points out that the oral feter, which is characteristic for malignant diphtheria, is as a rule indicative of anaerobic bacterial disintegration. Since the genuine diphtheria bacilli, in contradistinction to the pseudodiphtheria bacilli, may be grown under anaerobic conditions and thus have the capacity for anaerobiosis, the question could be asked whether strains of anaerobic diphtheria bacilli do not occur in some cases of malignant diphtheria. These anaerobic strains would differ from the aerobic strains in that they do not form a toxin that can be neutralized by antitoxin, but rather a different, still unknown irritant; for true diphtheria toxin develops only in the presence of sufficient amounts of oxygen and not under anaerobic conditions. The author states that two and one-half years ago he observed four cases of malignant diphtheria in which the aerobic culture failed during the first few days, but anaerobic culture yielded genuine diphtheria bacilli in from fourteen to eighteen hours. During the later stages of the disease the aerobic culture likewise yielded diphtheria bacilli. Since the observation of these cases the author has searched for similar ones but has not found any. However, a recent report by Doskočil in a Czech journal describes twelve cases of malignant diphtheria in which the anaerobic culture of diphtheria bacilli succeeded.

Serologic Diagnosis of Brucella Abortus Infection.—Laun and Heide call attention to the fact that Brucella abortus infection does not present a uniform symptomatology and that the term undulant fever is unsuitable. The positive outcome of the Widal and the complement fixation tests, or the positivity of either of these tests, is proof of the existence of a Brucella

abortus infection. It is advisable to add 2 per cent of glycerin to the agar pH 7.2 of the *Brucella abortus* cultures that are used for the Widal test. An addition of 0.2 per cent of solution of formaldehyde to the *Brucella abortus* suspension does not impair the Widal reaction. The authors obtained excellent results with a *Brucella abortus* suspension of great density, which contained twelve strains from human subjects and from animals, and to which a 0.2 per cent solution of formaldehyde had been added. Even after twelve months there were no changes in efficacy. The result of the Widal test can be read after two hours' storage in the incubator (37 C.). A further storage of the test material for twenty-two hours, either at room temperature or at incubator temperature, is without influence on the results. Agglutination of *Brucella abortus* by the serum of the patient is to be considered positive even if it occurs at only slight attenuation. A coagglutination of typhoid, paratyphoid and proteus bacteria was not observed. The Widal reaction revealed no differences between human and animal strains of *Brucella abortus* and between the serums from man and animals. Fluctuations in the stability of the colloids of human serums, as for instance during pregnancy, may be a source of error in the Widal test for *Brucella abortus*. If the complement fixation test is made with a 5 per cent suspension of sheep's corpuscles, varying doses of amboceptor and of complement should be employed, the value of which should always be determined on the day on which the experiment is made. The *Brucella abortus* extract should be studied for its efficacy at intervals of three months. All dilutes should be made with a sterile 0.85 per cent solution of sodium chloride. The positive outcome of the complement fixation reaction in a serum dilute of 1:62.5 (quantity of serum 0.02 cc.) proves the existence of a *Brucella abortus* infection. The agglutinin formation commences sooner than the formation of the antibodies that inhibit the hemolysis, but it also disappears sooner. The complement fixation phenomenon persists considerably longer.

Disintegration of Erythrocytes and Bilirubin in Malariotherapy.—Végh and Stanojević studied the connection between the disintegration of erythrocytes and the bilirubin content of the blood in twenty-one patients who had been inoculated with malaria but of whom only twelve developed fever attacks. In all except one of these patients the number of erythrocytes and the hemoglobin content decreased, while the bilirubin content increased, but decrease on the one hand and increase on the other did not run parallel; that is, there was no quantitative relation between the transformation of hematin or hemoglobin on the one hand and the increase in bilirubin on the other. It was observed also that the increase in the bilirubin content is rapid, while its elimination is slow. From these observations it may be concluded that some of the factors involved in these processes are still unknown.

Capillaroscopic Studies in Allergic Diseases.—Hantschmann and Steiner made capillaroscopic studies on persons with and without allergy. The incidence of atypical capillaroscopic pictures was much greater in patients with allergy than in those who were free from it. In persons without vascular disturbances the capillary pictures were normal in 66 per cent, slightly atypical in 27 per cent and greatly atypical in 7 per cent. Of the patients with allergy, only 20 per cent had normal capillary pictures, 43 per cent had slightly atypical pictures and 37 per cent had greatly atypical pictures.

Diagnostic Utilization of Disintegration of Leukocytes.—Nagy points out that the leukocytes with neutrophil granules disintegrate most rapidly but that there is a difference in the resistance to disintegration in the cells with toxic granules and in cells from the normal blood. He proved this by the following experiment: Several cubic centimeters of blood is withdrawn from the median vein (in 3 per cent citrate solution $\frac{1}{10}$) and is left to stand at room temperature. After an hour, several smears are prepared from the upper layer of the column of sediment and are stained according to May-Gruenwald-Giemsa. If the blood is normal, the leukocytes are nearly all normal, except that in some instances the marginal ones show slight changes. However, if the blood is from a patient having an infectious disease, hardly a single intact leukocyte can be found. The neutrophils are full of vacuoles and other signs of disintegration. Many of the monocytes show the same changes, while the lymphocytes retain their shape for a comparatively long period. The early disintegration is probably due to toxic granules. In spite of the fact that several authors deny the pathognomonic significance of the toxic granulations, because it is too greatly under the influence of the unevenness in staining and because it occurs irregularly and late or not at all, the author ascribes to it considerable diagnostic significance. He stresses that his method easily masters the technical difficulties and avoids the confusions that may result from individual estimation.

Observations on One Thousand Cases of Ovarian Cystoma. M. Randazzo.—p. 2381.

Posterior Lobe of Hypophysis, Eclampsia, and Nephropathy.—Anselmino and Hoffmann call attention to several former reports in which they attempted to prove that an increase in the hormone production of the posterior lobe of the hypophysis plays a part in the development of nephropathy and eclampsia in pregnant women, and then they review the histologic changes in the posterior lobe of the hypophysis of patients with eclampsia, which were recently described by Cushing. That author observed heavy infiltrations of basophilic cells in the posterior lobe, some of which had an adenoma-like character, and in the clefts of the tissue he observed large quantities of the secretory product of these cells. He considers these changes an indication of increased functional activity of the cells that produce the hormones of the posterior lobe of the hypophysis, and thus they present the anatomopathologic basis for the presence of the antidiuretic and pressor components of the posterior hypophyseal hormone in the blood of these patients, which had been demonstrated by the authors. They discuss the relations of eclampsia and nephropathy to that form of contracted kidney to which Volhard applies the term of pale hypertension and then call attention to the coincidence of occurrence of vasopressor and antidiuretic substances in the blood and urine and to the coincidence of histologic changes in the hypophysis in the two disturbances.

Local Hormone Therapy of Ovarian Insufficiency.—Stanca gives the history of a woman, aged 19, who had never menstruated and who, since the age of 16, had repeated epileptic attacks. The amenorrhea as well as the epilepsy proved refractory to all treatments. Pains in the region of the cecum, which were suspected to be caused by adhesions developing after an appendectomy, and a desire to inspect the internal genital organs, led to a laparotomy. The adhesions on the cecum were separated and 1 cc. of ovarian extract was injected into each of the ovaries. The postoperative course was uneventful, and twelve days later menstruation set in for the first time. But just as surprising as the menstruation was the complete cessation of the epileptic attacks. The menstruation occurred regu-

larly for three successive months, but after that it ceased again; however, the epileptic attacks did not recur. A number of months later, although the patient did not menstruate any more, she became pregnant. The pregnancy terminated in a normal birth and the woman had no further attacks of epilepsy. The period of observation since the intra-ovarian injection is now two and one-half years and the author assumes a complete cure of the epilepsy. In trying to explain this effect on the epilepsy he cites reports that indicate a connection between menstruation and epilepsy. Because the woman became pregnant in the absence of menstruation, he assumes a disturbance in the anterior lobe of the hypophysis. He thinks that, although he has only two positive observations on the efficacy of intra-ovarian injection of ovarian extract in amenorrhea, he is nevertheless justified in pointing out in which cases this measure should not be resorted to. He considers the intra-ovarian injection of ovarian extract inadvisable in amenorrheas caused by aplasia, infantilism or hypoplasia of the uterus or by jacksonian epilepsy, diabetes, malaria or tuberculosis, but he hopes that his method will be tried in suitable cases.

Primary Carcinoma of Lungs.—The incidence of primary carcinoma of lungs in the Soviet Union has risen in the last two decades to as high as 11.18 per cent of all carcinomas. Playd studied sixty cases of this disease confirmed at necropsy. He concludes that a definite diagnosis can be made by finding the cellular elements of the neoplasm in the sputum, in the pleural exudate, in the puncture of the neoplasm, or from a biopsy. Among the more valuable clinical signs the author mentions (1) early and repeated blood spitting, (2) signs of compression of the neighboring organs, such as dyspnea, hoarseness, aphonia and dysphagia, and (3) involvement of the regional lymph nodes, particularly of the supraclavicular and infraclavicular groups. Percussion and auscultatory signs are variable depending on the localization, the size and the relation of the tumor to the large bronchi, as well as on the accompanying alterations, such as pneumonitis, atelectasis and bronchiectasis. Muffled breath sounds in the beginning, together with a rapid increase in the area of dullness, are suggestive of a growing tumor. Metastases are common, principally to the liver and the central nervous system, causing dyspepsia, ascites and paralyzes. Pleural exudate was present in one third of the cases but presented nothing characteristic. Combination with active pulmonary tuberculosis was extremely rare. Tubercle bacilli were found in only one case. Cough was present in 80 per cent. Neither cough nor sputum was characteristic in any sense. Twenty per cent of the patients had night sweats. The temperature was normal in 50 per cent, was frequently subnormal and, at times, raised and hectic. Localization of pain was inconstant and not typical. The blood picture presented a hyperleukocytosis, neutrophilia and lymphopenia, more rarely erythropenia, hemoglobinemia and monocytosis, and never eosinophilia. Serum reactions are not characteristic. The roentgenologic examination is of the greatest value and was responsible for a high percentage of correct diagnoses. The increasing frequency of the disease, as well as the therapeutic possibilities in its early stages, suggests that it be treated as a social problem in specially created institutions.

Treatment of Edema and Ascites with Large Doses of Calcium Chloride.—Gurevich reports the effect of large doses of calcium chloride on edemas due to various causes. His observations were made in fifteen cases in which the usual diuretics were not effective. The patients were on a salt-free diet and limited water intake. He concludes that calcium chloride is a powerful diuretic. Daily doses of from 10 to 30 Gm. did not give rise to any untoward symptoms. In four

patients there developed nausea and anorexia, but these symptoms disappeared on withdrawal of the drug and were not present when the exhibition of the drug was resumed a few days later. The diuretic effect becomes manifest only after a number of days, occasionally weeks. Calcium chloride is frequently capable of producing a diuresis when other diuretics have failed. Large doses may produce an exacerbation of a nephritic process while acting as a diuretic. The calcium chloride is effective when salt is eliminated from the diet.

Bibliotek for Læger, Copenhagen

126: 383-427 (Sept.) 1934

*Disturbances of Alimentary Tract as Result of Avitaminosis. E. Schjodt.—p. 383.

Disturbances of Alimentary Tract Resulting from Avitaminosis.—Schjodt sees a close connection between disturbances of the alimentary tract and avitaminoses. Avitaminoses may develop from gastro-intestinal disorders, but these disorders are an integral part of the symptom complex of avitaminoses. A vicious circle may thus occur. Writers on avitaminoses due to vitamin A, B₁, B₂ and C deficiency mention anorexia, vomiting, diarrhea, achlorhydria, stomatitis, gastro-intestinal atrophy and gastric ulcer as symptoms; most of them are found in all the avitaminoses mentioned, both in men and in animals, with atrophy most marked in lack of vitamin A, achlorhydria in lack of vitamin B and gastric ulcer in lack of vitamin C. The author says that in his experiments on rats on a diet without vitamins B₁ and B₂ a number of the symptoms appeared, but not atrophy or achlorhydria; there were also in the majority of cases peculiar capillary hemorrhages from the stomach or intestine, gastric hemorrhage occurring more often after vitamin B₂ deficiency and intestinal hemorrhage in vitamin B₂ deficiency. Most of the disorders appear as early symptoms in vitamin deficiency. As in northern countries the diet or, at all events, certain forms of diet are low in vitamins and since vitamin deficiency may directly cause gastro-intestinal disorders, diets richer in vitamins are recommended in such disorders in these countries.

Remarks on Tuberculin Tests in Finnish Army. M. Savolin.—p. 776.

*Chronic Circumscribed Arachnitis. R. Gordin.—p. 791.

Chronic Circumscribed Arachnitis.—Gordin regards this disorder as a secondary ailment in processes with symptoms of meningism. The most common causes are infection and trauma; other causes are insolation, circulatory disturbances in the central nervous system and tumor in the nervous system. He says that arachnitis due to trauma occurs as a reactive process depending on alteration of blood vessels and hemorrhage and cannot actually be considered an inflammatory disturbance; it might perhaps be termed a "traumatic meningopathy." The symptomatology in chronic arachnitis on the whole agrees with that of tumor in the central nervous system. The arachnitis usually appears in a predominately cerebral or spinal form. Encephalography is helpful in the cerebral form and myelography in the spinal form. The periodic course of the disorder and the history of trauma or infection are also significant. Close observation of all details in the picture and course often allow correct diagnosis. Disturbances considered simply psychogenic after apparently slight traumas should receive greater attention. Treatment is operative, and the prognosis is relatively favorable. When intracerebral or intramedullary changes are present, the prognosis is less favorable. The operation should not be terminated too soon in uncertain cases, even with positive results in the arachnoid, as the arachnoidal changes might be due to an intramedullary or intracerebral tumor. Twelve cases, five of cerebral and seven of spinal form, are reported.

CARDIAC CONDITIONS INDICATING THERAPEUTIC ABORTION

HAROLD E. B. PARDEE, M.D.
NEW YORK

Two very different sorts of criteria have been used as a basis for the management of patients with heart disease during pregnancy. Formerly the anatomic diagnosis was relied on almost exclusively, and the demonstration of a marked mitral stenosis or of a markedly enlarged heart was considered to be so serious a complication of pregnancy that interruption was often advised when these conditions were found. The prognosis was thought to depend on the character of the pathologic changes.

During the period between 1912 and 1919 the functional ability of the heart came to be better understood. It was realized that this was not definitely dependent on the character of the pathologic changes and that if a measurement of functional ability could be devised this would afford a better guide to the expected behavior of the heart during pregnancy. Sir James Mackenzie¹ in 1921 pointed out certain errors resulting from attempts to rely solely on the pathologic diagnosis. He tried to avoid these errors by combining with the pathologic diagnosis an estimation of what he called the "limitation of the field of response to effort" and with a search for "signs of approaching heart failure" such as "a slight increase in the respiratory rate" and "the appearance of persistent râles at the lung bases."

In 1922 I advocated dependence on an estimation of cardiac functional capacity derived from the patient's history of past and present disability, combined with the reaction to exercise at the time of observation. A series of cases that had been grouped and followed in this way was reported from the Lying-In Hospital of New York City.² After 1924 the functional classification that had been introduced by the New York Heart Association³ was used in the cardiac antepartum clinic of the Lying-In Hospital, for it was considered inadvisable to have one functional classification for cardiac patients who were pregnant and another for those who were not.

From the New York Hospital and the Department of Obstetrics and Gynecology and the Department of Medicine, Cornell University Medical College.

Read before the Section on Obstetrics, Gynecology and Abdominal Surgery at the Eighty-Fifth Annual Session of the American Medical Association, Cleveland, June 13, 1934.

1. Mackenzie, James: *Heart Disease and Pregnancy*, London, Oxford University Press, 1921.

2. Pardee, H. E. B.: *The Fitness for Pregnancy of Patients with Heart Disease*, J. A. M. A. 78: 1188 (April 22) 1922; *Pregnancy Complicating Heart Disease*, Am. J. M. Sc. 164: 847 (Dec.) 1922.

3. Committee on Cardiac Clinics of the New York Association for the Prevention and Relief of Heart Disease: *Requirements for an Ideal Cardiac Clinic and a System of Nomenclature of Heart Disease*, Boston M. & S. J. 189: 762 (Nov. 15) 1923.

The basis of this functional classification is the patient's history of her ability to perform the ordinary physical activity of her everyday life, without unusual shortness of breath or palpitation. The patient's statements as to her ability to exercise are combined with an observation of the pulse rate and the respiratory reaction after a rather strenuous test exercise performed in the presence of the physician. According to the results of this method, cardiac patients are divided into four categories as follows:

Class 1. Patients with heart disease who are able to undertake ordinary physical activity without discomfort, such as palpitation or dyspnea, and who perform the test exercise without unusual tachycardia or dyspnea.

Class 2 A. Patients whose ordinary activity is slightly limited because of the appearance of dyspnea, palpitation or fatigue, and who show somewhat excessive tachycardia and dyspnea after the test exercise.

Class 2 B. Patients whose activity is greatly limited because of the appearance of dyspnea or palpitation and who show marked tachycardia and dyspnea after the test exercise, or who are unable to complete it.

Class 3. Patients whose activity is so limited as to make them unable to walk about without dyspnea or palpitation and who are so evidently dyspneic after such slight efforts as getting into and out of bed or walking across the room as to make any other exercise test unnecessary.

This method of rating the functional capacity of cardiac patients may be applied to pregnant women if one bears in mind the fact that during pregnancy a certain degree of limitation of ordinary activities because of fatigue, dyspnea and palpitation is a normal feature.

The malaise of the early weeks and the size of the uterus after the fifth or sixth month impose handicaps on the cardiovascular system which result in a greater liability to the development of dyspnea or palpitation after effort at these times. One must compare the cardiac patient with a woman of similar physical habitus, the same stage of pregnancy and a similar degree of uterine enlargement.

Patients do not pass suddenly during pregnancy from the condition of class 1 or class 2 A to the condition of class 3. The trained observer will notice a transition into the class 2 B category before the severe failure of class 3 appears. It is at this time that proper cardiac treatment followed by proper obstetric management can do so much to save patients from going into severe failure. A patient in class 2 B can be successfully treated and is in no danger as long as she is cooperative and under competent cardiac supervision.

Reliance on this estimation of cardiac functional capacity seems to afford a better understanding of the

conditions preceding the appearance of severe cardiac failure during pregnancy and labor. Reports have been made of its application by physicians in this country and abroad with definite improvement in the ability to predict the clinical course.

It is possible⁴ for a woman with loud cardiac murmurs and considerable cardiac enlargement to go through pregnancy and labor without the development of severe failure, provided the cardiac functional ability places her in class 1. It has been learned that class 2 A patients are able to go through pregnancy and labor without developing serious symptoms, though they may occasionally show unusual dyspnea and tachycardia during labor. Class 2 B patients are in real danger from the strain of labor, but they may with careful supervision go through a successful pregnancy. If the labor is short, whether naturally so or aided in the second stage by a low forceps operation, most of these women may also pass through labor without cardiac overstrain. In the more severe cases, however, it is safer to deliver by cesarean section, for this operation seems to put less strain on the heart.

Results in Cases Treated from the Point of View of Cardiac Functional Capacity

The accompanying table illustrates the results in the 546 cases from the literature that have been followed from the point of view of cardiac functional capacity. The mortality in class 3 patients is 40 per cent; that in class 2 B patients is 4.7 per cent; in class 2 A patients it is 0.56 per cent and in class 1 it is zero. The mortality of the whole series of cases is 6.6 per cent.

From what has been said it is evident that therapeutic abortion will be indicated in cardiac patients only to avoid the likelihood of the severe grade of cardiac insufficiency seen in the patients of class 3, during the latter months of pregnancy or during labor. This danger is not present in the patients of class 1 or in those of class 2 A except as will be noted later. The danger is definite in those of class 2 B and is serious in those of class 3.

Most of the class 3 patients included in the table represent women who appeared at the hospital for the first time with severe cardiac failure, either in labor or in the later months of pregnancy. This dangerous situation will always arise in hospital practice but should not do so if patients can be properly followed from the beginning of pregnancy. With further experience in the management of patients of class 2 B it is likely

that the mortality will be greatly reduced. It must be emphasized that these reports represent the first efforts of the various observers to use this method. Further experience should certainly lower the mortality.

Patients who are found to be in class 2 A in the early months of pregnancy may be divided into two groups: those who were in this class before pregnancy and those who have been reduced to it from class 1 by the illness of the early months.

The latter patients improve as the malaise of the early months passes off, and they become class 1 patients again as they were before pregnancy. Patients who were in class 2 A before pregnancy should be under the close supervision of a competent cardiologist, even though experience shows that they are not likely to develop severe cardiac insufficiency. Occasionally during the seventh or eighth months of pregnancy, a bronchitis or some improper physical exertion such as a bout of house cleaning, a walk in a cold wind, or even a severe argument with a child or husband may temporarily reduce the patient to class 2 B, necessitating rest in bed and digitalis for a time to recover cardiac reserve. This is such a rare occurrence with patients in class 2 A that I feel that therapeutic abortion need not be considered for them unless one is certain that they will not cooperate properly as regards restriction of activity.

Patients presenting themselves before the fourth month in the condition described as class 2 B or class 3 are the ones for whom therapeutic abortion should be considered. It should never be performed, however, until after a proper course of treatment by rest and digitalis. Such patients are always improved by this, to some extent at least, and after improvement has progressed as far as it will and there has been no further improvement for two weeks, it is time to decide on the further management.

If the patient is now in class 2 A it will be possible for her to go through a supervised pregnancy, as has been outlined previously, provided she can avoid inadvisable efforts and will consent to delivery by cesarean section, should the cardiac reserve prove unequal to the additional demands at the seventh or eighth month and the patient again fall into class 2 B at that time. This course demands close cooperation between the patient, the physician and the obstetrician but has been successful on many occasions. I believe, however, that the safety of the mother in such a category demands a physician who is more familiar with the treatment of these cases than is the usual internist or practitioner. It demands one who has actually followed many cardiac patients through pregnancy.

If the patient after treatment in the early months is still rated as in class 2 B, the pregnancy should probably be interrupted, for the extra demands on the heart which will arise in the seventh or eighth month are likely to lead to class 3 cardiac insufficiency at that time, which is a more serious situation, both for treatment and for prognosis. If these patients cannot have the most expert advice, or if they are uncooperative and are not inclined to follow instructions as to the degree of activity allowed them, it is safer to terminate the pregnancy as soon as one has decided that two weeks of treatment has been followed by no further improvement of the cardiac function.

At this time the patient's condition will be better than it was before the treatment, and the risk of the operation will be decreased accordingly. If they can avail them-

4. Pardee, H. E. B.: Experiences in the Management of Pregnancy Complicated by Heart Disease, Am. J. Obst. & Gynec. 17:255 (Feb.) 1929.

selves of expert advice and will be able to follow it, avoiding the dangers of housework, shopping, arguments and other excesses, patients in class 2 B may often be carried safely through pregnancy to a delivery by cesarean operation. The one danger most difficult to guard against is that of a respiratory infection. A bronchitis puts a serious strain on a weakened heart and may be the cause of serious cardiac insufficiency.

Patients who have been in class 2 B throughout pregnancy and in whom more serious cardiac insufficiency develops in the sixth or seventh month usually respond fairly well to treatment by rest in bed and digitalis. No interference with pregnancy should be attempted until improvement has ceased for two weeks, and then their condition and their ability to lead a sheltered life until the child is viable must decide whether abortion is to be done immediately or whether the patient is to be carried through the next month or so to a cesarean delivery.

There are three complications of the cardiac picture that somewhat affect the prognosis and therefore modify the plan of management, which would be based solely on cardiac functional capacity as outlined. The most common of these is auricular fibrillation, and yet Carr and Hamilton⁵ found it only fourteen times in 500 cardiac patients at the Boston Lying-In Hospital.

A patient with auricular fibrillation is subject to a danger that does not affect other patients with the same degree of cardiac functional capacity. Thrombi seem especially liable to form in their hearts and the occurrence of emboli either in the lung or in the periphery is not at all infrequent in patients whose ventricular rate is not well controlled by digitalis, especially in patients who have the more marked grades of cardiac insufficiency that would place them in class 2 B or class 3. Because of these conditions a patient with auricular fibrillation in class 2 B runs a greater risk in going through labor and should never be allowed to do this. She should be allowed to proceed with pregnancy only if her heart rate can be kept to approximately normal by digitalis and if the exercise test does not cause great and prolonged tachycardia. Furthermore, one must be certain that she will take the digitalis regularly and will cooperate in observing the restrictions on her physical activity. If such a patient slips away from treatment for two or three months she is certain to reappear with serious cardiac insufficiency.

Patients in class 2 A with auricular fibrillation should be allowed to proceed with pregnancy only after the ability to control the heart rate with digitalis has been demonstrated and the patient's complete cooperation obtained. Though lapses in treatment may not be followed by such severe cardiac insufficiency as with class 2 B patients, yet there is some danger of emboli during pregnancy and after labor. If the rate reaction after exercise is excessive under proper digitalis dosage, then these patients also had better be saved the danger of labor by the use of cesarean delivery.

Congenital malformation of the heart is another rare condition in connection with pregnancy, occurring only twelve times in the 500 cases reported by Carr and Hamilton.⁵ It, too, seems to have a special significance in pregnancy, for the mortality in their twelve cases was 16 per cent (two cases) compared to a mortality

of 5.8 per cent in 472 cases with rheumatic heart disease. Unfortunately, they have not made a functional grouping of their cases, so that one does not know in what categories these twelve cases would have been found. They state, however, that in patients who have a congenital deformity allowing a right to left shunting of the blood, the typical symptoms of cardiac insufficiency may not develop but, without showing any disability before delivery, the patients may suddenly develop rapidity of the pulse and respiratory rates without venous congestion and die slowly or quickly of asphyxia or exhaustion. This occurred only after delivery by cesarean section or podalic version and not after delivery by more normal means. My personal experience has not included such observations, and further experience with the functional grouping is needed before it can be said in what type of patient with a congenital cardiac defect there is an indication for a therapeutic abortion.

The third special condition affecting the prognosis is the presence of bacterial endocarditis. This, too, is rare, being found in less than 1 per cent of cases. The maternal mortality is high, but, after all, the mortality of patients with this disease is so great that little danger can be added by pregnancy. Surprisingly enough, the fetal mortality in these cases is low, so that it would not seem that the presence of this condition need be considered an indication for abortion.

When a patient has a history of a previous abortion because of heart disease, the question must arise as to how much influence this event should have on the management of another pregnancy. One should ascertain as closely as possible the condition of the woman at the time the abortion was performed and decide whether cardiac insufficiency of class 2 B or class 3 grade was present. If so, there is danger of a recurrence; if not, the fact that an abortion was performed may be disregarded as a point in cardiac prognosis, for it has been performed so often in the past because of the presence of loud murmurs or of a large heart with quite adequate functional capacity.

If abortion is decided on, the type of operation to be selected will depend on the stage of the pregnancy, on whether it seems advisable to sterilize the patient at the same time and on whether her condition makes it safe to prolong the operation by the time necessary to do this.

In the first three months vaginal procedures do not seem to disturb the circulation greatly, but when pregnancy is to be interrupted in the fifth, sixth or seventh month, the heart will be less disturbed by an abdominal operation. Local anesthesia is often very satisfactory in patients who are temperamentally suitable, avoiding as it does the rapid breathing and consequent exertion associated with a general anesthetic. If a general anesthetic is used, special attention should be paid to the avoidance of cyanosis.

If the patient has developed such severe cardiac insufficiency as to indicate therapeutic abortion, even if the decision has not been made until the seventh month, it is unlikely that she will ever again be able to go through with a pregnancy. In these patients sterilization as well as abortion seems indicated unless the economic factor has been important in preventing the woman from having adequate rest during pregnancy. If with improved finances and better opportunity to rest she might have a child, sterilization had better be avoided. The pro-

5. Carr, F. B., and Hamilton, B. E.: Five Hundred Women with Serious Heart Diseases Followed Through Pregnancy and Delivery, *Am. J. Obst. & Gynec.* 26: 824 (Dec.) 1933.

longation of the operation due to the sterilization procedure should be safe enough in a patient of class 2 B but not in a patient of class 3.

SUMMARY

1. The occurrence of class 2 B cardiac insufficiency not improved by treatment in a patient during the fifth, sixth and seventh months of pregnancy is an indication for therapeutic abortion. An exception may be made (a) if the patient is anxious to have a child, (b) if she is able to have expert cardiac guidance during the remainder of the pregnancy, (c) if she is willing and financially able to cooperate with the physician as to restriction of activity and (d) if she is willing to be delivered by cesarean section before labor, should this become advisable.

2. The occurrence of 2 B cardiac insufficiency not improved by treatment in a patient during the first three months of pregnancy is an even more imperative indication for abortion, for the patient must face the possibility of more marked cardiac insufficiency at the sixth or seventh month and, also, the possibility of miscarriage. Exceptions to this rule are very rare.

3. Patients first appearing with class 3 cardiac insufficiency must be treated medically before the subsequent procedure is decided on. In no case should operative procedures be undertaken until after a proper course of medical treatment.

4. Patients having auricular fibrillation and certain ones with congenital cardiac malformation must be considered as running a greater risk than others in the same functional class.

160 East Sixty-Fourth Street.

ABSTRACT OF DISCUSSION

DR. BURTON E. HAMILTON, Boston: I disagree with Dr. Pardee's emphasis on the importance of an effort test. There is no effort test that is a trustworthy estimate of the heart's functional ability. Many hundred cases with heart disease followed through pregnancy at the Boston Lying-in Hospital have taught the following simple facts: Unless a heart presents definite enlargement, a diastolic murmur, a loud systolic murmur usually with a thrill, or a dangerous disorder of the heart beat, it will not fail in pregnancy. Many neurasthenic patients, without these signs, give poor response to effort tests but never develop heart failure during pregnancy. Any case showing one of the foregoing signs of serious heart damage may show heart failure during pregnancy. Failure may develop suddenly. Strict regimens for these seriously damaged heart cases can make an extraordinary difference in the death rate. A natural death rate of at least 10 per cent can be reduced to 1 or 2 per cent. Therapeutic abortion is advised (1) when a patient has already failed and (2) when there is a complication in itself dangerous. These are simple, reasonable indications. No one has disputed them. With one of these indications, therapeutic interruption of pregnancy before the child was viable was done about fifty times in 550 cases in which there were severely damaged hearts. Nine of these showed complications, including auricular fibrillation, hypertension, nephritis and pulmonary tuberculosis. Heart failure had already been present in the others. The majority of these cases showed indications for interruption before pregnancy started. The majority of the women had had no adequate advice, some failed to follow advice, and a small number tried to follow advice but became pregnant despite it. A completely enlightened community would require few therapeutic abortions for cardiac indications. Are therapeutic abortions for cardiac reasons entirely avoidable? Very few patients who are under adequate control fail for the first time in the early months of pregnancy. When such a patient fails, this almost

never occurs before the sixth month. Then proper treatment of the failure usually does not necessitate sacrifice of the child. Rarely unforeseeable complications, such as severe pyelitis, may develop early in pregnancy in a cardiac case and require therapeutic abortion.

PHASES OF CARDIOVASCULAR AND RENAL DISEASE INDICATING ABORTION

W. W. HERRICK, M.D.

NEW YORK

In meeting the just demand that the expectant mother be safeguarded from needless jeopardy to life and future health, the obstetrician and the internist have a common task. While the offices of the obstetrician are indispensable, those of the medical man, though less exigent, may play no small part. In their mutual attempts to lessen maternal mortality and morbidity during gestation, labor or the postpartum follow-up period, no procedure is so often debated as abortion—the termination of pregnancy before viability of the fetus has been attained. Among the conditions in which this question arises, none are more frequent and few require more discriminative judgment than those involving cardiovascular-renal conditions. Although modified by pregnancy, these are primarily medical and not surgical disorders. As studies advance the internist often recognizes in eclampsia, in the nephroses and nephritides of pregnancy and in the milder types of so-called toxemias old friends in disguise. In extensive follow-up work from year to year the course and end of the larger part of this group unfolds itself in the familiar forms of hypertensive cardiovascular disease or of true nephritis.

An understanding discussion of abortion in relation to disorders of this kind calls for classification, a separation into various clinical and pathologic types and a brief consideration of each, especially in their relation to pregnancy. Here one at once enters a realm in which opinion and debate prevail. For clinical purposes one can recognize two leading types of the diseases in question: (1) those primarily involving the secretory mechanism of the kidney (these may be subdivided into (a) the degenerative lesions or nephroses, and (b) the inflammatory lesions or nephritides) and (2) those primarily vascular in origin. The more detailed grouping under these headings is illustrated in table 1.

NEPHROSES AND ABORTION

Among the salient features of nephrosis are edema, abundant albuminuria, usually without blood and with relatively few casts, diminished urinary output, tendency to anemia and an inversion of the ordinary albumin-globulin ratio of the blood serum. Further, hypertension does not occur in the ordinary nephrosis. In the lipid form these symptoms are intensified, a general anasarca develops, there is a strikingly lowered basal metabolic rate little influenced by thyroid medication, and great susceptibility to infections especially pneumococci. The microscopic examination of the kidney shows all grades of cloudy swelling or parenchymatous degeneration, largely tubular in localization and without

From the Departments of the Practice of Medicine and of Obstetrics and Gynecology, College of Physicians and Surgeons, and from the Presbyterian Hospital and the Sloane Hospital for Women.

leukocytic infiltration or other changes characteristic of an acute inflammatory process and without notable damage to the vascular mechanism. In the lipid forms extensive infiltration of the renal parenchyma with fatty material is characteristic.

The etiology seems to be a toxin or a disturbance in circulation. Among the poisons which may provoke such renal degeneration are included those of the pyogenic cocci, the tubercle bacillus, and *Spirochaeta pallida* and such metallic agents as lead, arsenic and mercury. Among the vascular disturbances obstruction to the venous outflow from the kidney, as in chronic stasis, and alterations in volume and quality of arterial blood supplying the kidney may be etiologic factors. It is possible that a nephrosis never exists in a pure state but is always complicated either by a glomerulonephritis or by a disturbance in the renal circulation. Examples of the latter are the vascular obstruction which seems to be so important an element in certain toxemias of pregnancy, also the narrowing of the arterial stream bed as observed in advanced renal arteriosclerosis of any type.

So far as I can discover no example of pregnancy in a patient with true lipid nephrosis established before

TABLE 1.—*Classification of Cardiovascular-Renal Diseases*

C. Arteriosclerosis
1. Secondary to essential hypertension, general arteriolar and arterial sclerosis; probably includes "malignant hypertension"
2. Secondary to chronic glomerulonephritis
3. Primary arteriosclerosis, may include:
(a) An acute necrotizing form as "malignant hypertension"
(b) Chronic, decrescent or senile arteriosclerosis

conception is on record. In view of the fact that an amyloid nephrosis is the result of severe and long continued infection, such as tuberculosis, neglected syphilis and chronic sepsis, this complication of pregnancy must be rare indeed.

A nephrosis is a serious threat to the life of the fetus and to the security of the mother. If albuminuria is persistent and increasing and if any degree of edema is present, one is amply justified in emptying the uterus. If one waits until there is great diminution in the output of urine and a general anasarca the fetus is doomed and too often the mother as well. A history of nephrosis of the simple type need not bar further pregnancies nor need subsequent pregnancies be interrupted because of the history of the previous nephrosis—provided the signs of the disturbance vanished shortly after delivery and the patient showed no evidence of disease of the kidney in the interim between pregnancies.

Chemical nephroses occurring during pregnancy, the most frequent example of which is the kidney in corrosive mercuric chloride poisoning, may demand special management. Important factors are the degree and duration of the nephrosis and the stage of gestation. In a case of corrosive mercuric chloride poisoning of mild degree early in pregnancy, the regenerative capacity of the kidney might be sufficient to effect repair so that

the fetus would not be affected unfavorably. Occurring late in pregnancy a metallic nephrosis would almost surely lead to fetal death and greatly increase maternal hazards. In the acute phases of a chemical nephrosis a hands-off attitude is essential. Any addition to maternal burdens, such as induced abortion, is generally injudicious. With survival of the acute stage, persisting evidence of serious renal damage in the form of albuminuria, edema or hypertension suggests the need of ending a pregnancy almost sure to result in fetal death and in increased risk to maternal life and future health.

The so-called kidney of pregnancy, while it is a degenerative process and therefore falls into the group of nephroses, can hardly be dealt with on such a simple basis. While some milder forms may be pure nephroses, it is probable that most, if not all, have a vascular component which may be fundamental. The rôle of vascular spasm in the nephric disorders of pregnancy is one which is subscribed to by many component authorities. The association of hypertension with a majority of the examples of the degenerative kidney of pregnancy and the results of follow-up studies in revealing persistent vascular disease in large numbers of these patients make it clear that the general run of such cases cannot be judged primarily or exclusively as renal disorders but must be dealt with in their relation to the rest of the body, especially to the circulatory system. The relation of the so-called kidney of pregnancy to abortion will be discussed under a later heading.

NEPHRITIDES AND ABORTION

Scientific nomenclature should be strict. The term "nephritis" has been used loosely and too often in connection with conditions that have no suggestion of renal inflammation. It should be confined to the inflammatory processes in the kidney and their sequelae. At present it is the fashion to call these glomerulonephritis. The condition may be focal, embolic or diffuse; it may be acute or chronic and with or without edema. Its cause is infection, usually with the streptococcus, the initial focus most often being in the upper air passages, the tonsils, paranasal sinuses, pharynx or bronchi. At the onset, fever is usual. Albuminuria, usually of high degree, is constant. Hematuria is obligatory in the early stages. Hypertension is almost always present and occurs early, usually coincident with or shortly after the appearance of the albuminuria. An anemia of the secondary type is characteristic. There is a strong tendency to retention of nitrogen, to albuminuric retinitis, and eventually to uremia. In cases with enduring hypertension, sclerotic changes take place slowly or rapidly in the vascular tree. Clinically the end stage of nephritis can be differentiated with difficulty or not at all from the advanced stages of primary vascular disease with hypertension in which an unusual amount of nephrosclerosis has taken place. Often only careful records of the origin and course of the disease make the distinction clear. However, at the necropsy the pathologist separates these two conditions with assurance. Because of the difference in reaction to pregnancy of primary nephritis and primary vascular disease with hypertension, this separation is important.

Often nephritis is latent or so mild that its manifestations are intermittent and therefore may be undiscovered until the increased burden of pregnancy brings the process into the open. In this event albuminuria becomes marked and persists. Red blood cells

and casts appear in the urine. Lessened fluid output and edema follow quickly. Hypertension, while not necessarily present, is usual. Albuminuric retinitis, anemia, nitrogen retention, drowsiness and uremic convulsions may follow. These symptoms may occur in almost any combination or in any grade of severity. No medical complication of pregnancy offers a greater threat to the fetus. Placental infarction and separation, fetal death and spontaneous delivery, often of a macerated fetus, may be expected in about 60 per cent. To this ill prospect of a successful outcome of pregnancy is added the fact of a decline in the efficiency of the maternal kidney as a result of prolonging the pregnancy. Together these present a strong argument for abortion in cases of proved nephritis.

One may summarize the indications for abortion in nephritis as follows: If the disease is manifest at the time of conception, abortion should be done promptly. If the disorder has been latent and arises early in pregnancy, and if it is marked by a considerable albuminuria which tends to increase despite treatment, it is unlikely that pregnancy can succeed. In the interest of maternal welfare it should be terminated. If to albuminuria is added edema or hypertension, this action becomes obligatory. If the symptoms of nephritis do not appear until the second half of gestation, a somewhat different attitude is to be taken. One is confronted with the question whether or not the pregnancy can be carried to the period of viability. In such a situation much judgment and often not a little courage are required. If the nephritic symptoms are mild and do not progress rapidly, delay may be safe and the child may survive despite albuminuria, edema and hypertension. However, if the disturbance advances and if to these cardinal features are added serious visual disturbances, threatening blindness, advancing nitrogen retention, deviations from normal mentality, twitching, greatly exaggerated reflexes or convulsions, the uterus should be emptied promptly without regard for the fetus.

Of great practical importance is the procedure in subsequent pregnancies. Once a woman has exhibited a true nephritis in pregnancy, she is almost certain to show a similar process when reproduction is attempted again. The disturbance in a subsequent pregnancy is likely to appear earlier and is generally more severe and therefore prone to end even more disastrously for child and mother. Once the fact of nephritis has been established the safe reproductivity of the patient is at an end. Early abortion adds little to fetal mortality in cases of this kind and does much to promote maternal health and security.

CARDIOVASCULAR DISEASE AND ABORTION

Judging from the report of studies in the toxemias of pregnancy from many obstetric clinics, the distinction between primary cardiovascular disease or essential hypertension and nephritis is confined largely to the internist and as yet has been recognized by few obstetricians. The work of Mussey and his associates¹ in the Mayo Clinic is an exception to this rule. Since the work of Allbutt, Janeway and others, the differentiation of these two important conditions has become increasingly clear and in medical wards the habit of placing the label "nephritis" on every case showing hypertension no longer obtains. In considering cardiovascular-renal

disorders, exactness in the use of terms is called for in order to bring out the differences in etiology, in course, and in prognosis and treatment of primary nephritis and primary vascular disease, differences which should be understood in their relation to pregnancy because of their practical value as well as their theoretical interest. My conception of the distinguishing features of these two diseases is given in table 2. The differences set forth in table 2 bear on the problem of abortion.

The clinical features of nephritis in association with pregnancy have been described; in the end stages the clinical features of primary vascular disease of the kidney during gestation present a different picture. In essential hypertension the internist recognizes the typi-

TABLE 2.—Distinguishing Features of Nephritis and Vascular Disease

	Nephritis	Vascular Disease
Etiology	Infection, usually streptococci	Inherited vasomotor instability
Features of onset	Sudden fever, albuminuria, hematuria and edema, with or without hypertension	Insidious, vasomotor instability, exaggerated rise of blood pressure and pulse rate under stress
Albuminuria	Constant and early	Never at onset; develops later
Hematuria	Constant and early	Never, excepting late after nephrosclerosis develops
Casts	All kinds	Rare; few hyaline only
Amount of urine	Scanty	Normal or polyuria
Blood pressure	Not always high; if present constantly elevated	Intermittently high; very variable excepting in terminal stage when fixed high
Retinal picture	Albuminuric retinitis; exudate, edema, hemorrhages, sclerotic changes late	Vascular retinitis; spastic arteries; sclerotic changes secondary to hypertension; hemorrhages late; cotton wool patches
Blood	Anemia; nitrogen retention early	No anemia; often plethora; no nitrogen retention excepting terminal
Infection	Increased susceptibility	Resistant
Kidney involvement	Primary; inflammatory and degenerative	Secondary and late as result of vascular spasm or sclerosis; degenerative never inflammatory
Arterio-sclerosis	Secondary; often of rapid development	Secondary; often of slow development but may be rapid
Course	Relatively short	Relatively long
Cause of death	Uremia or infection	Apoplexy; cardiac failure; renal failure, 5% to 10%
Pathologic changes	Tubular and glomerular inflammation, with cellular increase, epithelial crescents and glomerular adhesions; vascular changes slight or absent, largely confined to kidney	changes in vessels and glomeruli; thickening of capillary walls; cellular increase slight or absent

cal background of inheritance and personality, the exaggerated sensitiveness and responsiveness to life as revealed in unusual vascular or hypertensive reaction to physical or mental stimuli. In the course of years the occasional hypertension becomes continuous, though still variable beyond the normal. The arterioles are spastic, later becoming sclerotic. This process selects mainly the arterioles of the retina, spleen, pancreas, heart, brain, liver, lung, voluntary muscles, mesentery and kidney. The regional involvement varies greatly in each case—a fact largely determining the cause of death. There is great resistance to infection and absence of anemia. Death is typically by cardiac failure or apoplexy. The course extends over years, varying from two years in the malignant cases to twenty-five years in the milder types. The latter may merge with the senile or decrescent form of arteriosclerosis, a variety in which the larger arteries are affected chiefly.

1. Mussey, R. D., and Keith, N. M.: Significance of Nephritis of Pregnancy. J. A. M. A. 91: 2044 (Dec. 29) 1928.

The relation of this process to the kidney is very important. In the early phases of the average case in which vascular spasm seems paramount the kidney is little affected. As renal arteriosclerosis takes place along with sclerosis in other parts of the vascular tree there is still little outward sign of renal damage. Only when arterial narrowing so reduces the blood supply of the kidney that the factor of safety is trespassed on does albuminuria occur from a secondary renal degeneration or nephrosis. Excepting in the hyperacute conditions such as eclampsia, this is a late feature and usually indicates a speedy breakdown somewhere in the vascular system. In only 5 per cent or at most 10 per cent of such cases is this in the kidney. Usually apoplexy or cardiac failure end the story. Clinical evidence of renal damage may be lacking altogether.

The result of a prolonged study of the medical disorders of gestation and an attempt to correlate many of these with general medical conditions is the opinion that the thread of this primary vascular disease runs through most if not all of the toxemias of pregnancy that are not strictly in the nephritic group. In eclampsia and preeclampsia arterial hypertension is the presenting symptom. From study of the retina and the capillaries much evidence can be had favoring arterial spasm as the essential basis of the renal and hepatic degeneration that may attend these disorders. Particularly impressive is the record of the follow up of patients who have suffered eclampsia, preeclampsia, or other forms of late toxemia not primarily nephritic in origin and which have been called such terms as recurring toxemia, nephritis, and substandard kidney. As so frequently happens, the obvious sequelae of their toxic pregnancy presented by patients of this kind are usually much more suggestive of primary cardiovascular disease than of nephritis. Corwin and I² pointed this out in the clinical study of 275 cases of toxemia of pregnancy from the Sloane Hospital for Women.

Recently Tillman and I³ reported 594 cases with a prolonged follow-up. Of the ninety deaths in this series, seventy-two, or 80 per cent, were from causes within the circulatory system or the kidney. Eleven necropsies were done. In these the pathologist confirmed the clinical opinion in reporting two types of cardiovascular-renal disease. The first group of four cases showed the changes characteristic of chronic glomerulonephritis; the second, including seven cases, showed those of hypertensive cardiovascular disease.

As studies have progressed, an increasing amount of data points to certain tentative conclusions. The eclampsias, preeclampsias and other forms of late toxemia marked by hypertension, with or without the late development of albuminuria and edema, mild or severe, with or without recurrence in subsequent pregnancies, in their clinical behavior and in their necropsy observations belong among or are allied to the primary cardiovascular disorders. To place the label "nephritis" or "substandard kidney" on these is to be lax in the use of terms or unaware of an important differentiation now quite generally made in medical wards and by that court of last resort, the pathologist.

The question of abortion in relation to these vascular types of toxemia will now be considered. If the disorder antedates conception one is confronted with the probability that in the second trimester the blood pressure will become increasingly elevated. This may be the sole disturbance for several weeks or until the systolic pressure reaches from 180 to 200, when suddenly an albuminuria of variable amount, a gain in weight, edema and a decline in renal output may occur with or without rapid progression to fetal death or to maternal convulsions with or without evidence of damage to the liver. In general, few women with a systolic pressure consistently above 140 or a diastolic pressure of 100 or over at the beginning of pregnancy escape some of these disturbing symptoms. The higher the blood pressure the greater is the risk. The general policy in cases of this kind when eagerness for offspring consents to place immediate maternal safety and subsequent maternal health in some jeopardy is to carry on until the systolic pressure rises above from 170 to 180 or the diastolic pressure above from 110 to 115, or until persistent albuminuria occurs. Early in pregnancy this situation demands prompt emptying of the uterus. If previous pregnancies have shown serious hypertension, one should view seriously cases with a systolic blood pressure constantly above from 150 to 160 or a diastolic pressure above from 100 to 110 in the first trimester.

In women showing rise of blood pressure after conception the attitude varies with the period of gestation in which the rise takes place and with its rate of progress. It is to be kept in mind that the majority of the toxemias fall into this group in which hypertension is the initial and at times the only disturbance; appearing well after conception, with slow progress and without other features, until the blood pressure reaches high figures, usually about from 170 to 180 systolic. At this point development is quite rapid. The picture of a nephrosis may unfold itself in albuminuria, in diminished urinary output and edema, or in evidence of hepatic degeneration by epigastric pain and tenderness, perhaps with jaundice, or the picture of eclampsia may be presented. It is true that nephrosis in pregnancy or examples of eclampsia occur without the initial hypertension. However, these are among the rarities and need not disturb the procedure to be outlined in the average case.

The events described may take place in rapid sequence. In this case there should be little delay in emptying the uterus, particularly if there is unsatisfactory response to treatment. In the acute forms one may be taken unawares and advanced symptoms present themselves without previous opportunity to come to a decision. In acute eclampsia or in cases with a great decline in urinary output and marked edema, it is often well to allow nature to take its course. This is usually death of the fetus and its expulsion promptly or after a delay. The ending of intra-uterine life marks the end of the progress of toxic symptoms. If this occurs spontaneously, the mother is spared the added strain and risk of intervention.

In the larger group the progress is slow and decision can be made in a more leisurely fashion. If hypertension begins in the first trimester and is progressive, the pregnancy is usually doomed to failure in proportion to the early appearance and the rate of progression of the circulatory disorder. Blood pressures persistently

3. Herrick, W. W., and Tillman, A. J. B.: Clinical and Necropsy Findings in Cases of Toxemia of Pregnancy with Prolonged Follow-Up: Their Relation to Cardiovascular and Renal Disease, read before the Association of American Physicians, Atlantic City, N. J., May 2, 1934.

above 150 systolic and 105 diastolic, especially if progressive, are usually indications for abortion in the first trimester. If albuminuria appears and persists, or if epigastric pain and tenderness, icterus, persistent vomiting or such symptoms as excessive activity of the reflexes or deviation from normal mentality are seen and do not yield to treatment, the argument for intervention is unanswerable.

In the second and third trimesters, the point of view is modified by the possibility of carrying the pregnancy to the point of viability of the fetus. In this stage of gestation, therefore, moderate degrees of hypertension, while an indication for caution, may not in themselves demand intervention. However, the appearance of marked albuminuria, retinal edema and exudate, separation of the retina or other signs of serious adverse progress permit little delay in ending the pregnancy. This action is fully justified on several grounds. In pregnancy marked by disturbances that seem to be primarily vascular in nature, the more serious types have little promise of fetal survival because of infarction, apoplexy or premature separation of the placenta. In the more acute types there is a threat to the maternal life. In the subacute types the mother is in little immediate danger but the risk to her future health is great. In eclampsia, preeclampsia and the less acute forms of toxemia also marked by vascular disturbances, the follow-up studies are illuminating. At least 50 per cent eventually develop cardiovascular disease with hypertension. Continuing pregnancy in the presence of such disorders or undertaking pregnancy when these have been manifest in previous pregnancies is to court chronic invalidism.

As in other medical problems, one must take account of the exceptions. Occasionally an example of chronic cardiovascular disease with hypertension and with well marked arteriosclerosis will go through one or more pregnancies without mishap. In my experience most of these patients have been Negroes. Again, a condition of hypertension antedating or appearing soon after conception or late in the gestatory period will not progress and may not appear in a subsequent pregnancy. In considering an individual situation these exceptions must be regarded, rare though they be. Follow-up studies seem to reveal the fact that such cases do not merit separate classification since they are not exempt from the ultimate consequences of their cardiovascular instability and should be regarded as examples of potential circulatory disease.

CONCLUSIONS

From a medical point of view the toxemias of pregnancy seem to fall into two groups. The first and smaller group includes the nephritides. These are examples of primary nephritis and to these alone is the term "nephritis" strictly applicable. The feature of this group is prolonged and marked albuminuria with a tendency to anemia, edema and uremia. Hypertension is not obligatory. Cases of this kind do badly in pregnancy and usually require abortion when nephritic symptoms are manifest and do not yield to treatment. Repeated pregnancies are practically always unfortunate in outcome, leading to fetal death and acceleration of the downward course of the disease in the mother.

The larger group of toxemias seems to include the eclampsias, preeclampsias and the large number of milder disturbances variously classified under such terms

as "recurring toxemia," "nephritis" and "substandard kidney." The dominant clinical feature of this group is hypertension. Nitrogen retention and uremia do not occur except rarely as the end result of renal arteriosclerosis. Albuminuria is usually absent. When it is present it is abrupt and late in appearance, variable in amount and, excepting in the hyperacute cases, is preceded by a considerable period of hypertension. During the acute phases of the toxemia, in the follow-up and at the necropsy in patients dying some years after the toxic pregnancy, one finds the stigmas of hypertensive cardiovascular disease rather than those of nephritis.

In this group the problem of abortion is usually less urgent than in the nephritic group. In the acute eclamptic cases abortion is usually unwise, as it adds greatly to the maternal burden at a most critical time. Recovery with continuation of the pregnancy or the more frequent event of fetal death and spontaneous delivery with relief of toxic symptoms may be looked for in all excepting the 15 per cent of mothers who die in the acute attack. Excepting in particular cases with special features, conservative medical treatment is safest. In subsequent pregnancies the evidence of cardiovascular disease with hypertension must be sought. The incidence of this disorder in about 50 per cent of those having had eclampsia, preeclampsia and the milder types of hypertension in former pregnancies cannot be ignored.

In the less acute types the decision as to abortion can be made in more leisurely fashion. If hypertension appears early in pregnancy and increases despite treatment, abortion is indicated. When to hypertension are added albuminuria and edema not yielding to treatment, the same action is advisable. If viability of the fetus can be attained by delay, this may be risked in selected cases under careful supervision. Always one must have in mind the adverse effect on maternal health of the prolongation of pregnancy under these circumstances. There is no better recipe than this for the production of chronic vascular disease. Repeated pregnancies are to be discouraged excepting in the mild cases appearing late in pregnancy and usually with little or no albuminuria or edema. Some of these do not recur when reproduction is again attempted. However, when all is said, it must be emphasized that each case is an individual problem to be solved on its own merits.

16 East Ninetieth Street.

ABSTRACT OF DISCUSSION

DR. ROBERT D. MUSSEY, Rochester, Minn.: The acute nephroses of pregnancy, unassociated with other conditions, such as arterial disease, are rare in pregnancy. I have never seen the acute severe nephrosis described by the author. I have made a diagnosis of mild lipoid nephrosis in several patients presenting late in pregnancy a marked edema, marked albuminuria without hypertension, without red cells in the urine, without retention of urea or of phenolsulphonphthalein in the blood, and without changes in the ocular fundi. These patients progressed to a satisfactory termination of pregnancy and had no further recurrence. Acute albuminurial nephritis of an infectious type as described by Dr. Herrick is unusual in pregnancy. This leaves the large group of nephroses, which, from the standpoint of obstetrics, may be divided into two general groups. These are, first, those conditions which include arterial and arteriorenal disease that existed prior to pregnancy, and, second, that large group of cases called preeclamptic toxemia. For those patients who have a preexisting arterial or arteriorenal disease before pregnancy and in whom the condition is definite and undoubted, abortion should be advised. But there are certain extremely mild conditions to which the term occult nephritis has been applied and in which the patient

under observation does not grow worse. Certain definite requirements may be laid down here to see whether the patient will have a reasonable chance of going through pregnancy: The patient should not have a systolic blood pressure over 150 and the urine should not have more than a definite trace of albumin. There should be no increase in the nonprotein nitrogen of the blood. The ocular manifestations of old trouble, if present, should be slight. The patient should have the ability to concentrate the urine to 1.025 and to dilute the urine to 1.003. Patients with undoubted chronic nephritis should be advised against becoming pregnant. On the other hand, a history of hypertension and of albuminuria, associated perhaps with a premature labor, is not definite evidence of chronic nephritis, and in some of these cases careful examination will reveal adequate arterial and renal function, so that the patient may be carried through. These cases also are rather rare. In addition to the hypertension, the albuminuria and the patient's symptoms, I have found the examination of ocular fundi of great importance in showing how to deal with severe pre-eclamptic toxemias. The examination with the ophthalmologist tells how much trouble there is. Repeated examination shows whether or not this is advancing and, lastly, the ophthalmologist is often able to tell when to terminate the pregnancy. Since last fall I have been using a test that has been described by Brown and Heins to measure the variability of the blood pressure in prenatal work. This test consists of a cuff on one hand. The other hand is placed in ice water for one minute. In thirty seconds after it is placed in there the blood pressure is taken. It is taken again at the end of one minute and the hand is removed from the ice water and two minutes later the blood pressure is taken, and every two minutes until it becomes normal. It has been found that in normal individuals the blood pressure returns to normal in ten minutes. In patients who have the so-called prehypertension type of blood pressure in arthritis the blood pressure takes a longer time to return to normal. There are indications that seem to point to its being possible to pick out these patients ahead of time.

INDICATIONS FOR THERAPEUTIC ABORTION IN TUBERCULOSIS

F. M. POTTENGER, M.D.

MONROVIA, CALIF.

In a specialty of medicine in which the success of treatment has made such rapid strides as in tuberculosis during the past quarter of a century, the prognosis, in the face of any complication, is subject to change from time to time.

Twenty-five years ago the coexistence of tuberculosis and pregnancy was considered so disastrous that a pregnant tuberculous woman was almost invariably advised to have the pregnancy terminated. The prognosis in tuberculosis today has become vastly more favorable; likewise the care given to the pregnant woman has changed immeasurably in her favor. So this question should be examined anew and the prognosis based on the facts possessed at this time. It is important to know to what extent, if any, the danger to a woman's life has been reduced by the modern methods of dealing with the complication of tuberculosis and pregnancy.

In order to determine this an endeavor should first be made to find out whether there is anything in the pregnant state that is inimical to the tuberculous patient, and, second, whether modern medical methods are able to overcome these unfavorable conditions.

While pregnancy is a normal physiologic state in which extraordinary demands are made on the patient's

metabolism but for which the organism is usually prepared to make necessary adjustment, tuberculosis is a pathologic condition which likewise makes extraordinary demands on the patient's metabolism but for which the organism is able to make necessary adjustment under some conditions but not under others; so the combination of these two conditions presents very serious problems which require special consideration from the physician.

Our problem for discussion is the extra hazard that is thrown on a woman suffering from tuberculosis by a complicating pregnancy. It probably can be best approached by discussing the special conditions that pregnancy brings about in the organism and by determining the influence that they may have on the patient from the standpoint of tuberculosis.

It is now well recognized that along with fecundation of the ovum and the stoppage of ovulation there comes a widespread readjustment of the endocrine system in which not only the ovary but the thyroid, pituitary and suprarenals bear an important part. The salt metabolism of the body too adjusts to the new physiologic demands. The physiologic balance is also disturbed in tuberculosis, the degree depending on the severity of the lesion and the particular constitutional characteristics of the patient. It stands to reason that pregnancy and tuberculosis, when present simultaneously, will require greater adjustment than either condition alone.

PHYSIOLOGIC DISTURBANCES BROUGHT ABOUT BY PREGNANCY

Many systemic reactions in pregnancy have been studied in an effort to determine the effect they might have on the tuberculous process. The result in most instances has been inconclusive. The following are some of the more obvious conditions that have been investigated:

It has been pointed out that the lipase content of the blood serum during pregnancy is lowered, reducing the lipolytic effect on the waxes of the bacillus and diminishing one of the natural antibacillary actions of the body. This effect, of course, is largely theoretical and is difficult to prove.

The increase in cholesterol which appears in the blood during pregnancy has been cited as favorable to the development of bacilli. Tuberculous guinea-pigs in which an increase in blood cholesterol was produced by feeding have been reported to show a more rapid dissemination and especially a wider spread of caseation than that of the control animals. Other experiments have failed to confirm these results.

The question of demineralization has been given much consideration. There is at times a change in the calcium-potassium ratio in the pregnant tuberculous woman in the form of a calcium deficiency, which, according to biophysical interpretation, means an increased permeability of cell membranes and an increased activity of the tissues. This has been pointed out as making the patient more susceptible to injurious influences. In order to supply calcium to the growing fetus some observers even cite instances in which they have noticed the absorption of calcium to take place from areas of healed tuberculosis in the lungs with a consequent reactivation of the lesions. Stewart and Percival state that the calcium demand in pregnancy increases from 0.006 Gm. per day in the early months to 0.6 Gm. at term.

Tuberculosis itself also may be accompanied by calcium deficiency, thus making necessary compensation more difficult.

It has long been pointed out that in pregnancy a condition of anergy is present, as shown in both weakened and reduced frequency of positive reactions to tuberculin. The number of reactions in pregnant women compared with nonpregnant women is reduced about 50 per cent.

Since the same lowered reactivity and absence of allergy is shown in the exanthems, influenza, cachexias and severe tuberculosis when the patient's immunity is waning, it is cited as definite proof of a decreased resistance to tuberculous infection. The interpretation of these conditions of decreased reactivity to tuberculin, which are brought on as a result of some complicating condition such as here mentioned, as meaning decreased resistance to tuberculosis seems to be well established. It must not be confused with the desensitization that comes on as the patient develops a greater tolerance for bacillary protein during the course of the disease, which at times may approach complete or almost complete desensitization.

The manner in which different conclusions may be drawn from the same premises is shown in the following interpretations of the effect of menstruation on the tuberculous patient. Some writer has said that the tuberculous woman kills herself through menstruation. This statement is based on the well established fact that the menstrual time is often accompanied by an increased activity in the tuberculous lesion, as evidenced by such symptoms as a rise in temperature, an increase in cough and expectoration, a spitting of blood, and not infrequently by formation of fresh metastases. The non-tuberculous symptoms too are often increased.

Recognizing this fact, some clinicians suggest the following analogy: that menstruation being the birth of an unfertilized ovum and pregnancy ending in the birth of a fecundated ovum are similar processes, but that the pregnancy, being accompanied by changes which are so much greater, is far more injurious to the woman. Others explain that pregnancy substitutes one physiologic process for another but one which for the time being relieves the woman from the menstrual ordeal and so should be helpful.

It seems well established that aside from the disturbed nutrition and temporary lowering of resistance, which is caused by the nausea and vomiting of the early months of pregnancy, the course of the tuberculous process is not infrequently favorably influenced during the later months, and again unfavorably influenced after birth of the child.

The slowing of activity in the later months and the increased postpartum activity have been observed sufficiently often to indicate that these conditions are something more than accidental. This postpartum activity has been accounted for in different ways. Some think it is caused by the involution of the postpartum uterus during which time protein substances are thrown into the blood stream, producing a nonspecific reaction in the tuberculous lesions; others think that certain substances, the formation of which is stimulated by the tuberculous infection, fix themselves to the antibodies and inhibit the protection which the antibodies would normally exert on the patient.

INFLUENCE OF THE MECHANICAL CONDITIONS OF PREGNANCY AND THE PUERPERIUM ON PULMONARY TUBERCULOSIS

The change in intrathoracic mechanics during pregnancy seems to me to be one of the most powerful forces which would be inclined to influence a pulmonary tuberculosis. It offers not only an explanation for the improvement that is witnessed in the later months but also one for the increased activity that so often follows delivery. As pregnancy progresses and the uterus enlarges, the intra-abdominal pressure increases and pushes the diaphragm upward. This acts in much the same way as paralysis of the diaphragm following an operation on the phrenic nerve. By decreasing the size of the intrathoracic space it aids the lungs, the volume of which is reduced by the tuberculous infiltration, in adjusting to this space which it must always fill; thus the pulmonary tissue is permitted to relax and conditions are brought about which favor healing. Unlike the phrenic operation, pregnancy does not paralyze the diaphragm, so it fails to remove the pull on the pulmonary tissue with its descent during inspiration and ceases to keep it elevated after parturition. In spite of this, however, the elevation alone, by lessening the intrathoracic space and maintaining the condition during the late months of pregnancy, may slow the activity in the pulmonary infection to such a degree as to bring about a temporary or even a permanent improvement.

Following delivery, on the other hand, the diaphragm, which has been elevated through the increased intra-abdominal pressure, descends, allowing the lung tissue to expand. This not only takes away the protection afforded by the previous elevation but brings about an extra hazard by causing increased respiratory and circulatory action in the dependent portions of the lungs; if the lung lesion is still active and discharging bacilli, it furnishes an opportunity for new infection to take place through the secretions which may be drawn down into the bronchi. It further brings about conditions that favor the absorption of greater quantities of toxins.

To my mind, this change in intrathoracic mechanics offers the most rational explanation of both the favorable influence that is noted during the time of the enlarging uterus and the ill effects that follow delivery, for it is recognized that decreased motion and relaxation of lung tissue are of great value in healing and that increased motion and increased tension in lung tissue not only interfere with healing but may favor both increased activity and the formation of metastases.

WHEN SHOULD ABORTION BE PERFORMED IN PULMONARY TUBERCULOSIS?

What is most desired in this discussion is information, if such is available, sufficient either to establish as a fact that the body is able to adjust to pregnancy and the development of the child, without prejudice to the woman's chance of successfully overcoming a tuberculous infection, or the contrary.

One would like to know whether the course of tuberculosis complicated by pregnancy is sufficiently constant and regular to permit the establishment of definite rules to guide future action. My experience would make me answer this question in the negative. There are so many variables concerned that each patient must be treated individually. Some of the variables that one is obliged to consider are the character of the lesion,

whether preponderantly proliferative or exudative, or whether it has taken on caseopneumonic characteristics; the extent and age of the lesion, from which an opinion may be gained as to the specific resistance of the patient; the general resistance of the patient as may be judged from her constitutional characteristics and environmental conditions, and her ability to avail herself of the best medical care for both the tuberculosis and the pregnancy.

Other variables on the part of the patient are the natural nervous and endocrine balance, whether she is a primipara or a multipara, the age of a primipara, the effects of previous pregnancies in a multipara, and the general attitude of the patient toward the pregnancy under the condition of her health.

In private practice among women who have been able to give themselves good care I always consider terminating the pregnancy if the disease is active and the condition has been discovered prior to the third month. My final decision, however, is determined very much by whether the patient will carry out the proper regimen of treatment, preferably in a sanatorium, both during the pregnancy and after delivery, and whether she will be relieved of the care of the child.

If proper care can be arranged and the patient apparently has good resistance, and provided the lesion is not extensive and is of the milder type, she may usually carry the child with safety. On the other hand, if the patient does not show evidence of good resistance and the tuberculous lesion is not of a mild type, and if the conditions for the mother during gestation and after confinement are not favorable, her safety will be best guarded by terminating the pregnancy at once.

My personal experience in terminating pregnancy has been far less favorable in those cases in which I intervened after the third month. The shock is usually considerable, and the operation is quite often followed by increased activity in the lung. It seems better to give such a patient the best possible treatment, pneumothorax being used if necessary, and to allow her to go on to term under the care of a skilful obstetrician so as to throw the least possible strain on her during and after confinement. In a primipara, cesarean section may now and then be the best way out. Under no circumstances should a mother with active tuberculosis nurse her child, and in case of open tuberculosis the safety of the child demands immediate removal from contact with the mother.

There is also a type of patient in whom, although the tuberculous lesion may be quiescent, a pregnancy should be treated with the same degree of seriousness as the active cases just described. I refer to patients who, on account of constitutional characteristics or because of bad environmental conditions, have been able to overcome a limited pulmonary tuberculosis only with great difficulty. Such patients are very apt to break down again under the strain of pregnancy, particularly if it occurs too soon following illness. I always advise the avoidance of pregnancy until two years has elapsed after the tuberculosis has healed, yet I often permit a woman of good physiologic balance who has attained an arrestment of a tuberculosis more recently than that to complete a pregnancy should it occur. It is advisable, however, for her to be under close observation during the entire time of gestation and for a few months after delivery. Multiple pregnancies in women who have successfully overcome pulmonary tuberculosis are, in my

experience, inadvisable and are not unaccompanied by danger to the mother. One pregnancy is usually stood all right—in many instances two; but I have seen an increasing number of patients break down after a third or more. Particularly is this true in instances in which the pregnancies occur close together.

With the more recent hygienic methods of treating tuberculosis, there is noted a decrease in the number of complicating metastases, a reduction in serious symptoms and a very definite increase in the number of favorable results obtained; which fact has taken away from the tuberculous patient a certain amount of protection that was formerly thrown about him. Because it is observed that the body will stand extra demands better than it did when the patient was treated less carefully, there is a tendency to underrate the serious load that tuberculosis throws on the body and to subject the patient to strains that may be harmful even though endured.

This has produced a bolder attitude toward a complicating pregnancy, yet one must always remember that while tuberculosis is curable, in many cases even when advanced, it is cured with difficulty; and the prognosis is reduced by every complication that throws an extra burden on the patient.

No matter how slight the lesion, any patient can overcome a tuberculous infection best if spared all unnecessary strain. So, while one may get by with an operation, a pregnancy or some other severe strain, the careful physician will shield his patient from all these when he possibly can.

Pottenger Sanatorium.

ABSTRACT OF DISCUSSION

DR. FRED L. ADAIR, Chicago: The marriage of a woman who has had or has a recognizable tuberculous disease raises certain problems aside from the possibility of contact tuberculosis. These are mainly questions relative to her reproductive life, as marriage per se has little influence on tuberculosis. It seems almost useless to discuss medical indications for the control of reproduction in these days when the general attitude toward childbearing is such that the woman should decide for herself what course to follow. Ethical consideration seems to be gradually passing into the background. Laws relative to the regulations and legal sanction of reproductive control are illogical and out of line with practice and present social and medical needs. The problems of contraception, sterilization, therapeutic abortion and management of pregnancy are major questions that arise in the care of the married tuberculous woman. It seems to be generally accepted that a woman with a healed tuberculosis may go through pregnancy with relative safety if she is under proper supervision and can receive adequate care. It is also agreed that conception should not take place in a woman with an active tuberculosis. One has to decide in these cases whether contraceptive methods should be used or sterilization performed. If the case is curable and the woman has not obtained her desired family, the former is the method of choice. In those patients with incurable or extensive processes or whose family is complete, sterilization is the procedure of choice. Therapeutic abortion is not indicated at any period of pregnancy except during approximately the first trimester. The method of procedure varies with the case. When subsequent pregnancy is desired, the uterus is emptied from below. If sterilization is deemed necessary, an abdominal hysterotomy with tubal resection is the procedure of choice. The indications for the performance of a therapeutic abortion are determined by (1) the activity, stage and type of disease; (2) the reaction of the patient to the pregnancy; (3) the social and economic condition of the patient and the availability of adequate care and treatment for the pregnancy. This

paper does not call for discussion of other phases of the relationship of pregnancy and tuberculosis, but it may be well to reiterate that the danger periods for the pregnant tuberculous woman are (1) the first trimester, (2) the period of labor and the immediate puerperium, and (3) the period of lactation.

LESIONS OF THE OPTIC NERVE AND RETINA IN PREGNANCY

HENRY P. WAGENER, M.D.
ROCHESTER, MINN.

In the course of an apparently normal pregnancy, various ocular conditions may be encountered in which the influence of pregnancy must be taken into consideration. Hemorrhage into the vitreous, embolism or thrombosis of one of the branches of the central artery of the retina, acute chorioretinitis, retinal detachment, acute keratitis and iritis, paralysis of extra-ocular muscles and of accommodation, retrobulbar neuritis and homonymous hemianopia have been reported. In each instance the bearing of pregnancy on the severity of the disease or on its response to treatment must be evaluated. In the majority of cases, however, pregnancy is not directly connected with the causation of these lesions, and treatment can be carried out along the same lines and with as good results as if the patient were not pregnant.

An interesting condition on which pregnancy does have a direct bearing but which has no very serious significance is hemeralopia, or night blindness, which may develop among poorly nourished pregnant women. This night blindness disappears promptly after delivery or when the proper amount of vitamin A is added to the diet.

I saw recently an interesting case of a pregnant woman with retinitis pigmentosa in which the field defects definitely progressed during the latter months of pregnancy but returned rapidly to their previous status after birth of the child. I doubt, therefore, whether the presence of retinitis pigmentosa in a case in which the patient is pregnant would be a mandatory indication for therapeutic abortion. The question of abortion or sterilization in cases of hereditary diseases, such as retinitis pigmentosa or Leber's disease (hereditary retrobulbar optic neuritis and atrophy), would seem to lie in the field of eugenics rather than in that of therapeutics.

Considerable interest was aroused several years ago by reports of contractions of the temporal fields of vision observed in the course of otherwise normal pregnancies. These contractions were supposed to be caused by physiologic hypertrophy of the pituitary body. The changes reported in the visual fields never have been quite characteristic of pituitary lesions, at least of those seen in association with tumors of the pituitary body, and their significance would seem to be doubtful. I do not think any cases have been reported in which the loss of visual fields was sufficient to warrant consideration of interruption of pregnancy.

The conditions in the eye which are of more definite concern with reference to the question of therapeutic abortion are those for which some type of toxemia of

pregnancy is definitely responsible. Included in this group are optic neuritis, retrobulbar neuritis and hemorrhages in the retina seen in association with pernicious vomiting, and eclamptic amaurosis, angiospastic retinitis and detachment of the retina, which occur in the hypertensive toxemias of the later months of pregnancy.

The ocular complications of pernicious vomiting of pregnancy seem to have received relatively scant attention. They are rather rare, are seen apparently only in severe cases, and are of serious prognostic import. In 1932, Stander¹ reported two cases of hemorrhagic retinitis without edema of the disks. In both cases pregnancy was terminated artificially, in the second case immediately, but, in the first, not until eight days after the onset of hemorrhage into the retina. The first patient died, the second recovered. Stander expressed himself as regarding the appearance of hemorrhagic retinitis in pernicious vomiting as an absolute indication for immediate termination of pregnancy. These hemorrhages probably are an indication of a severe general toxemia, which is evidenced at times also by optic neuritis or retrobulbar neuritis with very rapid and marked loss of vision. Optic neuritis usually is a terminal manifestation, and the patient is likely to die in spite of immediate termination of the pregnancy.

Schiötz² reported two cases of retrobulbar neuritis; one patient died and one was still alive at the time of the report one week after abortion. The two cases recently reported by Tillman³ probably belong to this group; at necropsy, petechial hemorrhages and miliary focal necroses were found in the brain. Tillman's third patient, with a condition described only as "retinal hemorrhages," recovered, although bilateral flaccid paralysis of the lower extremities and the Korsakoff syndrome were in evidence. Masters'⁴ case in which the outcome was fatal probably also was optic neuritis. It is difficult to evaluate the terminal rise of blood pressure in this case, as the blood pressure was low in the other cases that have been reported. I have recently seen, in a case of pernicious vomiting, bilateral, intense, optic neuritis that progressed to complete blindness in from twenty-four to thirty-six hours. The pregnancy was terminated, but blindness persisted and paralysis of the extra-ocular muscles developed. Examination of the spinal fluid did not give evidence of meningitis, but the patient died a few days later. Necropsy was not obtained.

It would seem that lesions of the retina and optic nerve in pernicious vomiting may be of more frequent occurrence than is generally assumed. It would be well to make more frequent ophthalmoscopic examinations in these cases to learn whether warning symptoms appear in the retina before toxemia reaches an incurable stage. It is well to emphasize that, if in such cases and in cases of hypertensive toxemia examination is deferred until the patient has definite disturbance of vision, little can be done by the ophthalmologist except to give a serious prognosis.

With eclamptic amaurosis I have had little personal experience. In the most typical cases, a sudden, almost complete loss of vision occurs coincident with, or shortly

From the Section on Ophthalmology, prepared in collaboration with the Section on Gynecology and Obstetrics, the Mayo Clinic.

2. Schiötz, Hjalmar: Ueber Retinitis Gravidarum und Amaurosis eclamptica, *Klin. Monatsbl. f. Augenh.* 67: 1-136, 1921.

3. Tillman, A. J. B.: Two Fatal Cases of Hyperemesis Gravidarum with Retinal Hemorrhages, *Am. J. Obst. & Gynec.* 27: 240-247 (Feb.) 1934.

4. Masters, R. J.: Routine Ophthalmoscopic Examination as an Aid in the Management of Maternity Cases, *Tr. Am. Ophthal. Soc.* 31: 416-458, 1933.

before, the onset of convulsive seizures, and no visible lesions are present in the retina or in the optic nerve. The pupil retains its reaction to light. In some cases eclamptic amaurosis may be superimposed on a previously existing, mild retinitis, but the loss of vision is out of proportion to the visible involvement of the retina and of the optic nerve. Often, by the time the patient regains consciousness, vision has considerably improved or returned to normal. The attack may be so transitory that it escapes observation or is regarded as a nervous or hysterical manifestation. Sometimes vision returns more slowly.

Schiötz reported fourteen cases of eclamptic amaurosis. In only two of these did the condition occur as early as the seventh month of pregnancy. In a few of his cases in which the return of vision was gradual, he was able to demonstrate homonymous hemianopia during the period of recovery. He expressed the opinion that eclamptic amaurosis was to be regarded as *bilateral homonymous hemianopia due to a transient lesion, probably edema, of the visual centers in the occipital lobes*. Schiötz expressed the belief that the prognosis was always favorable in these cases and that eclamptic amaurosis never was to be regarded in itself as an indication for immediate termination of pregnancy. The condition seems to be identical with uremic amaurosis, the prognosis of which is equally favorable.

The ocular lesion which has most aroused the combined interest of the obstetrician and ophthalmologist is the retinitis that occurs in association with hypertensive toxemia. This interest has centered in the diagnostic significance of the retinitis, especially with reference to the question of chronic nephritis, in its prognostic significance to the future health and vision of the mother, in its indications for termination of the existing pregnancy, and in its bearing on the advisability of future pregnancies. The answers to the last two questions must be based directly on the interpretation of the first two points of interest.

Attempts have been made to demonstrate that different types of retinitis occur in different types of toxemia and that "albuminuric" retinitis is always diagnostic of chronic nephritis. As has been evident from the reports of Schiötz and of Corwin and Herrick,⁵ among others, retinitis can occur in any type of toxemia in which hypertension is a feature. The differences described appear to be those of stage and degree rather than of type of retinitis. Earlier investigators especially stressed the edema, hemorrhage and exudation that make up the picture of retinitis, and apparently they paid little attention to the retinal vessels, although Silex⁶ stated that the prognosis was worse in cases of retinitis with definite changes in the retinal vessels.

It remained for Mylius,⁷ however, to demonstrate conclusively that changes in the arterioles preceded retinitis and were, in all probability, the local cause of it. The changes in the arterioles are primarily spastic in nature and the retinitis is therefore of angiospastic type. It seems most logical to assume, therefore, that in hypertensive toxemia of pregnancy, as in glomerulonephritis and essential hypertension among nonpregnant patients, lesions in the retinal arterioles and resultant

lesions in the retina proper are to be interpreted simply as evidences of injury to the arteriolar system rather than as signs of any particular cause of this injury. Interpreted in this way, it seems to me that the obstetrician can use the information furnished by ophthalmoscopic studies of pregnant women to much greater advantage than in attempting to separate different types of toxemia by their aid.

As shown by Mylius, in the absence of retinitis changes in the retinal arterioles may be present which may be purely organic (sclerotic), spastic, organic and spastic, or spastic followed by organic. If organic changes are present in the arterioles at the first examination in the early phases of toxemia, it is obvious that the patient has suffered previous injury to the arteriolar system, as a result either of chronic nephritis or of essential hypertension. If spastic changes are present, or develop either alone or superimposed on organic changes, it is strongly suggested that toxemia is causing an active arteriolar lesion which, if not controlled, will result in retinitis and in new or increased organic injury to the general arteriolar system. It is not always possible to tell at a single examination whether changes seen in the retinal arterioles are spastic or organic, but repeated examinations usually will establish the diagnosis. When diffuse retinitis has developed as the result of arteriolar spasm, organic injury to the retinal and systemic arterioles will almost always be present. This is the reason for the prevalence of chronic nephritis or persistent hypertension among toxemic patients who have had retinitis.

From the standpoint of vision, the prognosis of retinitis of the toxemia of pregnancy usually is good. Most of the patients, even those who have had very diffuse retinitis, regain normal, or only slightly impaired, vision. It is true that the longer retinitis persists in its active phase the more injury will be done to the retinal tissues and the less complete will be the return of function to the optic nerve and retina. The duration of the retinitis and the amount of edema of the optic disk and macula are of great importance to future vision. In the majority of cases, however, the end results are surprisingly good.

The prognosis with respect to the future health of the mother is not so favorable, however. It is possible that spastic changes in the retinal arterioles can pass gradually into organic lesions without the appearance of retinitis. It is also possible that individual cotton-wool patches and hemorrhagic areas may appear in the retina without the presence of demonstrable organic lesions. It is true, however, that the development of cotton-wool patches and hemorrhages are at present the best available sign of the probable onset of the organic phase of arteriolar disease, and it seems quite improbable that diffuse edema of the retina and extensive exudation and hemorrhage can occur without spasm severe and prolonged enough to produce some permanent injury to the walls of the arterioles of the retina.

It is of interest that histologic studies of the arterioles of muscles obtained at biopsy or at necropsy disclose changes that fairly closely parallel the degree of arteriosclerosis demonstrable with the ophthalmoscope. The organic changes seen in the retinal arterioles after diffuse retinitis probably are accompanied by an approximately equal degree of injury to the arterioles throughout the body. It is obvious, then, that the great

majority of these patients will have persistent hypertension after termination of pregnancy. Thus, Schiötz, in follow-up studies, found evidence of chronic renal disease in twenty-seven of thirty-three cases of retinitis of the toxemia of pregnancy, and Masters in twenty-five of thirty-two similar cases. Seventeen of Schiötz's patients and thirteen of Masters' gave no evidence of nephritis before pregnancy.

Schiötz.....	17	3	16	4
Masters.....	13	3	10	4
Wagener.....	7	1	7	1

My eight patients with diffuse retinitis all showed residual, persistent hypertension; only one had had hypertension previous to pregnancy. Of eight patients with only a few cotton-wool patches and hemorrhages, five had residual, persistent hypertension.⁸ Only one had had hypertension previous to pregnancy. Thirty-eight patients had spastic or organic changes in the retinal arterioles, but retinitis did not develop. Only five of twenty-four patients who had not had hypertension previously gave evidence of persistent, residual hypertension. In only two of fourteen patients who had had hypertension was there residual increase in the severity of the hypertensive disease.

It seems obvious, then, that the development of retinitis in any case of toxemia of pregnancy is a serious menace to the future integrity of the vascular system of the mother, and that the occurrence of angiospastic retinitis is by no means limited to cases in which there is preexisting hypertension or chronic nephritis.

If a patient who has not had antepartum care enters the hospital in the latter weeks of pregnancy with symptoms of toxemia and diffuse retinitis, immediate interruption of pregnancy unquestionably is advisable, not only for the preservation of vision but in the hope of minimizing the residual, permanent injury to the arteriolar system. Unfortunately, cases of this type are still seen. The majority of patients with toxemia of pregnancy, however, are seen nowadays before retinitis develops. In such cases it is my personal opinion

that diffuse retinitis should not be allowed to develop. In order to forestall its development, frequently repeated ophthalmoscopic examinations should be made to follow the development and course of the spastic lesions in the retinal arterioles. If, in spite of conservative management, the spastic lesions become more marked, termination of pregnancy should be urged at the first indication of localized hemorrhage or of exudation into the retina.

I believe that the beginning of retinitis marks the onset of irreparable organic changes in the arterioles and that a delay of a few days may result in considerable injury, which could be avoided by prompt termination of pregnancy. If the fetus is of viable age, or if the toxemia and retinitis appear so early that it is obviously impossible to continue the pregnancy to the stage of viability, nothing evidently is to be gained by waiting. The most difficult problems for decision arise in cases in which the spastic lesions and retinitis develop at the stage of questionable viability of the fetus. When retinitis develops before viability, and pregnancy is allowed to continue for several weeks in the hope of obtaining a viable fetus, the chance of accomplishing this would seem to be too slight to justify the risk of increased injury to the vision and to the cardiovascular system of the mother. Thus in Schiötz's series of seventeen patients who had retinitis before the twenty-eighth week of pregnancy, only four were delivered of living babies; sixteen of these patients had residual hypertension. In Masters' series, thirteen patients had retinitis before the twenty-eighth week of pregnancy; only four gave birth to living babies; thirteen had residual hypertension. I have seen seven patients with retinitis before the twenty-eighth week; only one of these gave birth to a living baby; seven had persistent

hypertension. Only one of these patients had had hypertension before pregnancy (table 1).

Schiötz saw twenty patients with eclampsia who did not have retinitis; ten of them were delivered of living babies and none of them had persistent hypertension. Masters saw four patients with toxemia before the twenty-eighth week of pregnancy who did not have definite retinitis; two of these gave birth to living babies; three had residual hypertension. Seven patients seen at the clinic had toxemia before the twenty-eighth week of pregnancy but did not give evidence of retinitis. Three of these gave birth to living babies. Two had persistent hypertension; both had hypertension prior to pregnancy. It would seem, then, that in cases in which retinitis develops before the twenty-eighth week there is only about a 25 per cent chance of the patient giving birth to a living baby, even if pregnancy is continued to the stage of viability, and there is almost 100 per cent risk of permanent, cardiovascular-renal injury developing (tables 2 and 3).

There is some question whether patients who have evidence of preexisting cardiovascular-renal injury have a chance of carrying through pregnancy without increased injury. From the standpoint of changes in the retina, the incidence of angiospastic lesions, and especially of retinitis, seems to be less in this group of cases than in those of acutely developing toxemia. Of a group of twenty-four cases in which patients had hypertension previous to pregnancy, in thirteen cases

8. Wagener, H. P.: Arterioles of the Retina in Toxemia of Pregnancy. J. A. M. A. 101:1380-1384 (Oct. 28) 1933.

retinal arteriosclerosis was present, but spastic lesions developed in only six cases, or 25 per cent, and retinitis developed in only two, whereas in a group of fifty cases in which patients had toxic symptoms but had not had previous hypertension, spastic lesions developed in thirty-eight cases, or 76 per cent, and retinitis developed in seventeen. In only four of the group of twenty-four cases in which there was preexisting hypertension was there evidence of an increase in the severity of hypertensive disease following termination of pregnancy. The presence of previously established organic changes in the retinal arterioles is not, therefore, of itself an indication for abortion. I do believe, however, that the finding of angiospastic lesions is a definite indication for interruption of pregnancy if the tendency to spasms is not promptly and definitely controlled by conservative measures.

Among a certain number of patients with toxemia of pregnancy, especially of the eclamptic type, detachment of the retina develops. The occurrence of detachment of the retina is quite generally recognized as a definite indication for the prompt interruption of pregnancy from the standpoint of preservation of vision. In some cases detachment is caused by the subretinal edema which is a part of severe, diffuse retinitis. In these cases the prognostic indications with regard to the future health of the mother are the same as those of any diffuse angiospastic retinitis. The prognosis with regard to vision is rather poor, since in the majority of cases in which there is retinitis complicated by detachment, the retinitis subsides slowly and leaves considerable residual injury to the retina and choroid. In a few cases the retinal detachment is primary in type, that is, it is caused by subretinal exudation of serous fluid which apparently comes from the choroid and is not associated with preexisting retinitis. In these cases the retina usually reattaches itself quite rapidly after termination of pregnancy, and the patient usually regains surprisingly good vision. These primary detachments of the retina do not seem to have the serious prognostic significance, with regard to the integrity of the vascular system of the mother, as do the detachments associated with angiospastic retinitis. In three cases of this type seen at the Mayo Clinic, hypertension did not persist after termination of pregnancy. Prompt intervention is indicated at the first sign of detachment of the retina, however, for the sake of the mother's vision, for unquestionably the longer the detachment persists, the less completely will the function of the retina be regained.

Considered purely from the standpoint of the risk of increased injury to vision, future pregnancies are not strongly contraindicated among patients who have had retinitis or detachment of the retina associated with toxemia of pregnancy. It has long been recognized that retinitis does not often recur in later pregnancies. It is of interest that, in my series, retinitis occurred in only one of nine cases of recurrent toxemia. The observation of the grade of residual sclerosis in the retinal arterioles is, however, an aid in determining the degree of diffuse vascular disease persisting in a case of previous toxemia of pregnancy. The decision as to whether such a patient should become pregnant again must be based, I think, on the clinical estimation of the functional ability of the injured kidneys and vascular system to withstand the extra strain imposed by pregnancy. In most cases in which patients have

had diffuse angiospastic retinitis, the residual vascular injury is sufficient to contraindicate further pregnancies. Patients who have had detachment of the retina without retinitis, however, may show little or no evidence of permanent vascular or renal injury, and future pregnancies may be uncomplicated. I have seen one such patient in whose case two later pregnancies were uneventful.

SUMMARY

The lesions of the retina and optic nerve which occur in pernicious vomiting of pregnancy indicate a severe grade of general toxemia that may prove fatal even if pregnancy is terminated promptly. Earlier and more frequent ophthalmoscopic examinations in cases of pernicious vomiting may serve to give timely warning that the pregnancy should be interrupted.

The development of any type of retinitis in a case of hypertensive toxemia of pregnancy is an urgent indication for the termination of pregnancy, not only because of the danger to vision, but also because of the implied certainty of permanent injury to the general vascular system. In cases in which hypertension develops or increases while the patient is under observation, careful watch should be kept for angiospastic lesions of the retinal arterioles, either primary or superimposed on previous organic changes. If the integrity of the systemic arterioles is to be preserved, pregnancy should be terminated, if possible while the arteriolar lesions are still in the angiospastic phase, and certainly at the first indication of the onset of retinitis.

ABSTRACT OF DISCUSSION

DR. A. J. BEDELL, Albany, N. Y.: By means of photographs it is possible to visualize, clarify and correlate fundus changes, so that all will speak the same language and refer to the same things. By means of stereoscopic fundus photographs, early changes are recorded. The fundus vessels vary in size, distribution and contour. In some eyes they are almost straight and in others markedly tortuous. When the central retinal artery is occluded there is widespread pallor of the fundus, soon followed by a definite contraction of the artery. If nature has provided a secondary circulation by means of the cilio-retinal vessels, the supply going to the macula is preserved and central vision remains undisturbed. Retinal hemorrhages may be single or multiple. They may come from a single ruptured vessel or from closure of the central retinal vein. The most important early vessel change is spasm. Hypertension plays an important rôle in the production of fundus changes. The diagnostic sign of terminal hypertension is the appearance of dark brown more or less rounded deep retinal or choroidal spots, which are diagnostic and not found in any other condition. When the ocular signs of toxemia are not recognized, the patient may develop a severe hypertensive retinitis. Many recover ocular function but some show optic atrophy, irregular areas of retinal degeneration, choroidal sclerosis and white dots. It is seldom that radiations are seen about the macular region such as are common in brain tumor and certain forms of nephritis. There is, however, an edema of the optic nerve, which is so localized and so extreme that to the inexperienced it suggests an intracranial growth when in reality it is the papilledema of hyperpiesia. As Dr. Wagener has stated, detachment of the retina occurs in some forms of toxemia. This may be unilateral or bilateral, and it is readily recognized by the lobulated gray movable folds of the retina. Those who are responsible for maternal care must recognize that ophthalmoscopy offers a valuable method for recognizing impending circulatory disasters. And so the message that we bring as ophthalmologists is early recognition of spasm of the retinal artery and the removal of the cause of that so as to prevent permanent hypertension.

INDICATIONS FOR THERAPEUTIC ABORTION

FROM THE STANDPOINT OF THE NEUROLOGIST
AND THE PSYCHIATRIST

CLARENCE O. CHENEY, M.D.

NEW YORK

The induction of abortion should be undertaken as reluctantly as one would commit justifiable homicide. If in the course of pregnancy some disease arises as a direct consequence of gestation, or if a woman suffering from disease is made much worse by the existence of pregnancy, and if her life is distinctly endangered in consequence, it is not only justifiable, but it is the physician's duty to terminate gestation, and thus to save one life, and that the more valuable of the two, instead of sacrificing both mother and fetus.

This statement by Hirst¹ is quoted as one setting forth, in my opinion, the fundamental principles to be considered in therapeutic abortion. My topic calls for a discussion of the indications for abortion in neurologic and psychiatric disorders under these principles; that is, a discussion of the neurologic and psychiatric disorders found in pregnant women which arise as a direct consequence of gestation or are made worse by the existence of pregnancy, so that the woman's life is distinctly in danger in consequence.

I may say at the outset that a review of the literature and my personal experience do not lead me to believe that there is any specific neurologic or psychiatric disorder which is in itself and without exception an absolute indication for the interruption of pregnancy. My opinion agrees with others who believe that not only the disease but its severity, its course, and the general condition of the pregnant woman have to be given consideration in the individual case. The problem would be rendered much easier if there were unanimity of opinion regarding conditions in the individual case which indicated abortion, but such is not the situation, and one would hardly expect it to be so in this problem any more than that unanimity exists in many other problems in the practice of medicine. I wish to present, therefore, the points of view on the indication of abortion of the various experts as recorded in the literature and finally to present briefly reviews of specific cases in which the question of abortion has arisen in my own experience.

As part of a symposium on the psychiatric and neurologic indications for interruption of pregnancy held in Vienna, May 18-19, 1931, under the leadership of the late Prof. Constantin von Economo, Prof. H. Herschmann² discussed the various points of view that he had obtained by a questionnaire method from directors of neurologic and psychiatric university clinics in Germany and Austria as well as from the directors of the neurologic divisions of some of the general hospitals. He inquired from these directors regarding their attitude toward therapeutic abortion in seventeen organic nervous diseases and received thirty-two replies, of which some were incomplete because of the lack of personal experience with the diseases inquired about. Some replies were generalizations; only a few were detailed.

Twenty-five experts expressed themselves on the question of the interruption of pregnancy in epilepsy. Six of these were against abortion in epilepsy. For example, Wagner-Jauregg said that he did not believe that abortion was indicated in epilepsy and that in cases of status epilepticus interruption comes too late or may be dangerous. Gaupp stated that there is no justification for interruption of pregnancy in epilepsy, maintaining that epilepsy is not made worse by pregnancy but that, on the contrary, one does see not infrequently that epileptic women have fewer attacks during pregnancy than at other times.

On the other hand, nineteen experts declared that epilepsy under certain circumstances presented a medical indication for abortion. Schlesinger held, for example, that genuine epilepsy was a compulsory indication for abortion. Bumke interrupts pregnancy in severe progressive forms of epilepsy and in status epilepticus. Ewald interrupts pregnancy, especially in those cases in which psychic deterioration appears during the pregnancy with epilepsy. According to von Economo, the indication is given in those cases in which the epileptic disease per se shows progression in the course of time and in which, in spite of medical treatment during pregnancy, an increase in attacks appears; also in those cases in which the attacks appear for the first time in pregnancy.

There were, therefore, three groups of opinions from these psychiatric and neurologic experts regarding abortion in epilepsy: those who completely deny indications, those who see indications in every outspoken case, and those who see indications under some conditions which, to be sure, are not clearly defined.

The same lack of unanimity of opinion and criteria is indicated by Herschmann in his report of the attitudes of the experts toward abortion in cases of the other sixteen diseases of the nervous system about which he inquired.

In multiple sclerosis some of the neurologists advocate therapeutic abortion on the ground that a rapid progress of the disease is noticed during pregnancy. Others in each diagnostically certain case of multiple sclerosis advocate abortion. Others point to the necessity of abortion in early cases on the ground that the patients may thereby be given a few years of bearable existence. Gaupp permits abortion in severe cases of spastic paraplegia but in other cases, especially if the child is wanted, he believes that the pregnancy may be allowed to proceed. Three experts on the other hand deny the necessity of interruption of pregnancy in multiple sclerosis.

Regarding exophthalmic goiter, thirteen of twenty experts replied that in their opinion abortion would be indicated in severe cases with decompensation and marked weakness. On the other hand, Hübner stated that he had not seen any case of exophthalmic goiter in which he would recommend abortion. Pötzl and Raimann spoke in favor of abortion in acute cases. Von Economo held that in cases of exophthalmic goiter in the early stages, as well as in cases in which the disease develops during pregnancy, abortion is indicated. There was no unanimity of opinion among the experts regarding the question of operative procedure in exophthalmic goiter in pregnant women.

Regarding abortion in tabes, some experts expressed themselves as positively in favor of it. Others were equally positive against abortion. Twelve experts indicated that in their opinion abortion might be indicated

Read before the Section on Obstetrics, Gynecology and Abdominal Surgery at the Eighty-Fifth Annual Session of the American Medical Association, Cleveland, June 13, 1934.

2. Herschmann, H.: *Neurologic Indications for Abortion*, *Wien. klin. Wchnschr.*, 44: 900-906 (July 10) 1931.

in tabetic patients suffering from exhaustion or a respiratory disorder or severe gastric crises.

Regarding chorea, seventeen of twenty-three experts were in favor of abortion in all severe cases, particularly when threatening cardiac symptoms or psychotic symptoms of a marked degree appeared.

The experts also differ regarding abortion in epidemic encephalitis. Some believed that in acute cases abortion was indicated; others said that in the chronic parkinsonian conditions abortion was likewise indicated but still others disagreed, stating that they had seen women with chronic epidemic encephalitis pass smoothly through pregnancy, giving birth to healthy children. Von Economo, who was acknowledged as the best authority on encephalitis, expressed the opinion that abortion was indicated in all acute cases of encephalitis and also in those chronic cases in which the condition was deteriorating. In other chronic cases von Economo might advise abortion because, during pregnancy, a dangerous aggravation of the condition may appear at any time.

Regarding polyneuritis, Bumke expressed the opinion that the development of this disorder during pregnancy was an indication for abortion if the polyneuritis was of a progressive character. Wagner-Jauregg said that the general status of the patient, particularly the condition of the circulation, had to be taken into consideration.

According to Bonhoeffer, abortion is indicated when hyperemesis exists simultaneously with polyneuritis because then the causal relationship between the pregnancy and the neuritis exists. He calls attention to the necessity of considering the cases in which marked residual paralysis of the abdominal and respiratory muscles remained after the polyneuritis.

Regarding syringomyelia, there was a difference of opinion. Some of the experts believed that in the uncomplicated cases there was no indication for abortion. Others thought the general condition of the patient had to be taken into careful consideration. Schlesinger, whose opinion was looked on as most authoritative, held that abortion was indicated only in those cases in which outstanding paralytic symptoms were present and, further, cases in which during an earlier pregnancy there had been a rapid progression of the spinal paresis. He also stated that with bulbar and vagus symptoms abortion was definitely indicated because in such cases experience had shown that during pregnancy there might be a progression of the disease, threatening life.

Regarding myasthenia gravis the majority of experts spoke in favor of immediate interruption of pregnancy, but several stated that abortion was indicated only under certain conditions. Gamper called attention to the fact that the course of the pregnancy was entirely undisturbed in some cases.

Regarding progressive bulbar paralysis, amyotrophic lateral sclerosis and progressive spinal muscular atrophy, the experts gave a large variety of opinions regarding abortion. Only seven of eighteen experts spoke in favor of abortion in each case. The remaining twelve responded variously, at times in part negatively.

Regarding the spinal cord degeneration associated with pernicious anemia, more than one half of the experts indicated that they had no personal experience with such cases. Of fourteen clinicians who discussed this point, eight spoke in favor of abortion in each case, four experts were in favor of abortion in each severe case, and one would wait to see whether during the

pregnancy there was a progression of the neurologic symptoms. One expert held that the neurologic symptoms in this disease gave no indication for abortion but that the decision depended only on the severity of the anemia and therefore rested with the internist.

Wagner-Jauregg held that brain tumor was an absolute indication for abortion; if the patient dies during advanced pregnancy, the child usually is also lost. On these grounds, as Pilcz proposes, in the advanced stages of pregnancy interruption should be made in the interest of the child. In other cases, Pilcz holds that abortion is not indicated. Von Economo pointed out that brain tumors usually progress rapidly during pregnancy, and he was therefore in favor of abortion. Schlesinger spoke in favor of abortion on similar grounds and also for the additional reason of the danger of a sudden increase of intracranial pressure. Other experts held that abortion is indicated in all cases of certain diagnosis of brain tumor.

Still other experts did not see any indication for abortion in cases of brain tumor. Some felt that in order to avoid the dangers of labor to patients with brain tumor artificial delivery should be made at term. Raimann distinguished between cases of brain tumor with a hopeless prognosis and those in which an intracranial operation was to be considered. If the brain tumor has a hopeless outlook then he believes that there is no excuse for abortion. On the other hand, Hübner would carry out abortion in such cases in which the disease picture is severe and is rapidly progressing. Meyer pointed out that if the tumor is localizable and operable one should carry out a radical operation. In such cases the postoperative course might unfavorably influence the pregnancy, and under these circumstances abortion should be carried out. In cases of nonlocalizable tumors the decompression operation should be done, but this is not so severe that the approach need interfere with pregnancy.

Herschmann concludes from these observations that the indications for abortion in cases of organic nervous disease are not sufficiently clear and that the problem must be studied in clinics because the opinions of the experts are based on individual, purely subjective criteria. Investigation is needed to determine which organic nervous diseases are apt to be aggravated by pregnancy. In such cases abortion must be recommended without question regardless of whether the condition appeared before or manifested itself at the time of the pregnancy.

Concerning the other organic nervous diseases in which the relation between pregnancy and physical and mental deterioration cannot be proved, one has to act differently, taking into consideration the appearance of the disease before or during the time of pregnancy. If the disease appears before the pregnancy one has to wait, and if it becomes worse abortion may be recommended. If the disease arises during the period of pregnancy, abortion should be recommended even if the pregnancy will not contribute anything of etiologic significance to the development of the disease. In his opinion, under all circumstances, indication for abortion is given in cases of dangerous disturbance of blood circulation, pernicious anemia, nephritis and cases in which during pregnancy grave psychotic symptoms are apt to develop into acute delirium.

Ware³ recently reported the cases of three paraplegic women in whom pregnancy was not interrupted, two

3. Ware, H. H., Jr.: *Pregnancy After Paralysis*, J. A. M. A. 102: 1833-1835 (June 2) 1934.

patients being delivered by cesarean section and the third with the assistance of midforceps. These cases present rather strikingly the fact that paralyzed women can go through a pregnancy successfully and have living children.

Kogerer⁴ discusses the problem of abortion in connection with mental disorders. In general it may be stated that abortion is justified in extremely dangerous situations in cases of manic and depressive psychoses. This is a matter not only of psychiatric indications but also of general medical indications. In women who have suffered several times from acute psychotic attacks after a period of pregnancy, Kogerer recommends that abortion be carried out in subsequent pregnancies in order to avoid other attacks.

Kogerer feels that the problem of relationship between pregnancy and schizophrenia is very important, difficult and contestable. The frequency of these cases and often their hopelessness demand an immediate and clear formulation of the problem, and the first question would be whether the pregnancy in general exerts an influence on the process of schizophrenia. He points to menstrual disturbances frequently seen in schizophrenic women, the decline of sexual libido, and the drop in the metabolism and the circulation and also in the other vegetative functions and endocrine systems.

Degenerative changes have also been reported in the gonads and suprarenals among schizophrenic patients by some investigators. A considerable amount of investigation proves that there are some changes related to pregnancy in schizophrenic patients, but less certain is the assumption of the influence of pregnancy on the chronic progressive forms. In such instances the objection might be raised that the disease would have progressed in the same way without pregnancy. It is therefore very difficult to decide whether abortion is to be applied in cases of schizophrenia. It is not easy to state whether abortion will have a possible influence on the psychosis.

Kogerer reports that in cases of paranoia and psychopathy opinion is against abortion. In cases of hysteria, one is led by somatic indications in solving the problem of abortion. In cases of psychoneuroses two situations are emphasized; the first one has to do with vomiting of pregnancy so far as it is psychically determined. In such a situation the physical condition will always determine the decision. The second situation has to do with psychogenic depression with danger of suicide on account of the unwanted pregnancy. Wagner-Jauregg justified abortion in the latter situation. Siemerling recommends the isolation of the patient with careful watching in order to save her from suicidal attempts. Kogerer is against such a plan and claims that isolation will have a pernicious influence on the patient.

Kogerer also states that he agrees with most of the authorities who expressed opinions to the effect that pregnancy has no unfavorable influence on the disease process in dementia paralytica and therefore abortion in this disease does not come into question.

Paul Nietzsche⁵ also discusses therapeutic interruption of pregnancy in mental diseases. He points out that abortion by physicians is permitted under the existing German laws only on therapeutic grounds and,

furthermore, only in cases in which there is great danger for the life or health of the mother.

In his opinion mental and nervous diseases very seldom justify the interruption of pregnancy. He states that aside from the eclamptic psychoses there are no specific psychoses of pregnancy, but psychopathic diseases are seen in pregnancy which also appear in other conditions. In a large majority of such cases it is not to be expected that the interruption of pregnancy would have a favorable therapeutic effect, but under all circumstances this measure is indicated in eclamptic mental disturbances as it is in eclampsia in general.

The attacks of manic depressive insanity are not conclusively influenced by the interruption of pregnancy.

Psychoses among the group of patients with schizophrenia give, in general, no indications for therapeutic abortion. However, certain investigators speak of these diseases being precipitated by pregnancy. Bumke raises the question, however, as to whether the bad effect that might be caused by pregnancy would be removed better through artificial abortion than through the natural process of birth. The possibility that pregnancy may cause further progression never gives an excuse for the sacrifice of the child in a disease such as dementia praecox with an unfavorable prognosis and an unpredictable course. Moreover, the condition of the catatonic pregnant woman can only exceptionally become so threatening that the interruption of pregnancy is indicated.

Nietzsche points out that others, for example, E. Meyer, hold that abortion is indicated in the case of a woman who has had several attacks of this disease in connection with previous pregnancies and then becomes pregnant again. In such cases, which are of infrequent occurrence, an intervention might be justified, but it is not justified in instances in which the course of the disease does not have such a definite relationship.

Although in the specific mental diseases there is very seldom an excuse for the interruption of pregnancy, the borderline conditions of psychopathy, neuropathy and hysteria are absolutely denied by Nietzsche as indications for abortion. One cannot emphasize that fact too strongly, he says, because of the fact that according to experience in these cases the danger exists that, on social grounds or because of considerations of comfort, nervous symptoms will appear in the foreground in order to make the physician susceptible. Also it is desirable to evaluate the emotional states in the pregnant woman, very carefully.

There are, however, mental disturbances occurring in pregnancy which justify intervention when all other methods of treatment have failed; but it is very seldom that these indications must be approved unconditionally. This type of illness makes its appearance in abnormal reactions in depressive moods, anxiety and fear, which are related to the pregnancy. The pregnancy complex stands in the center of these manifestations. It goes on to an anxiety state, tendency to suicide, emotional outbursts, animosity toward the husband, neglect of duties and loss of weight. In these cases the loss of strength becomes so considerable that severe danger ensues, and then the interruption of the pregnancy becomes necessary in case other forms of treatment such as psychotherapy and institutional treatment fail. However, careful conscientious psychiatric observation is unconditionally necessary before a decision is made regarding the indications and, as a rule, should be done in a clinic. A suicide complex cannot be recognized

4. Kogerer, H.: *Psychiatric Indications for Abortion*, Wien. klin. Wchnschr. 42: 906-909 (July 10) 1931.

5. Nietzsche, Paul in Bumke, Oswald: *Handbuch der Geisteskrankheiten*, Berlin, Julius Springer, 4, 1929.

per se as an indication for interruption of pregnancy in so far as a suicide fear is not a symptom of a psychotic condition justifying such a measure.

In an article on the effect of reproduction on insanity, Robinson⁶ reports on the replies of ninety-five British alienists to a questionnaire sent out by him, in which inquiry was made, among other things, regarding the indications for abortion in women with a history of cured mental disease and in women with active mental disease.

As a result of these inquiries Robinson makes the following observations:

The induction of abortion for the treatment of mental disease is evidently looked upon with little favor by the alienist and unqualified disapproval was expressed in the large majority of answers. It is clear that the scope of therapeutic abortion for both quiescent and active mental disease is very limited.

If it could be shown that conception may lead to permanent insanity in certain defined cases, then the termination of pregnancy would clearly be in the best interests of the patient, and the operation would conform to the desired standards; but the contrary appears to be the rule, for insanity initiated by pregnancy rarely persists, but tends to recover after a comparatively short period and in some cases may clear up spontaneously before full time is reached. Women who show permanent impairment of mentality following childbirth belong to the class of the potential psychotic for whom pregnancy is merely a subsidiary factor in the pathogenesis of insanity; upon the mentality of such a woman the operation of abortion cannot be curative and it may exert a deleterious effect that is more harmful than the continuation of pregnancy.

Little evidence has been brought forward to show that the induction of abortion has any positive therapeutic value in arresting the development of permanent insanity in women who are predisposed to that disease or may already be suffering from a mild but unrecognized form of it.

In connection with the problem of induction of abortion in threatened suicide, Robinson makes the following statements:

This argument in favor of abortion might be urged by any woman who is confronted with an unwanted pregnancy and it is therefore open to grave abuse; such threats may, however, be associated with true insanity and here there is unquestionably a real danger of the threat being carried out unless steps are taken to eliminate the risk by strict supervision of the patient or the termination of pregnancy. The physician in charge must be prepared to deal firmly with the patient's relatives who may attempt to force his hand; it is natural for the husband to seek an easy way out by operation in preference to certification and compulsory detention, but it must be pointed out that operation is not free from risk and that even successful intervention will not necessarily cure the mental symptoms or keep the patient out of an asylum; indeed the shock of surgical intervention may aggravate the mental condition and even precipitate admission to an institution.

Similarly, the patient's personal fear of recurrence may sometimes justify the termination of pregnancy. But it is not a sufficient reason for surgical interference in all patients who give a history of previous insanity because recurrence is not inevitable and much may be done to eliminate the risk by careful antenatal work.

It is clearly not possible to lay down any hard and fast rules concerning the use of therapeutic abortion on the grounds of threatened or actual insanity of the expectant mother, but each case must be judged on its own merits after due consideration has been given to the physical condition of the patient, her environment, the family record and the personal history, if any, of previous attacks of reproductive insanity.

I have reviewed some of the opinions of neurologists and psychiatrists on therapeutic abortion and briefly

report a number of specific cases of mental disorders, involving the question of abortion.

REPORT OF CASES

CASE 1.—An unmarried woman, aged 22, admitted to the Psychiatric Institute, had symptoms of a retarded depression which had existed for ten months. After two months' hospitalization she improved sufficiently to return home. Subsequently, a manic reaction developed. She became pregnant and was very anxious to have the pregnancy terminated at Sloane Hospital, where she was admitted. In the inquiry from that hospital regarding abortion it was said she appeared normal. I advised against abortion. The patient went through a normal pregnancy, was delivered of an apparently normal child, and has returned to her previous occupation. There is no evidence that gestation or labor has had a deleterious effect on her mental condition, and there is no certainty that the child will be abnormal.

CASE 2.—A married woman, aged 26, admitted to the Psychiatric Institute, had symptoms of a retarded depression. Four and a half months previously she had given birth to a child. She probably had a short period of elation and then had been depressed for three months before admission. After hospitalization for less than six months she was much improved. She had insight and a desire to return home and care for her child. Within five weeks she was readmitted in a manic state; she apparently recovered after eight months. After her return home she again became pregnant. On the recommendation of another physician, an abortion was performed. She soon became depressed and was again hospitalized seven weeks after the abortion. She again recovered after six and a half months but soon developed a manic attack and was committed to a state hospital, where she has remained for the past year. Obviously the interruption of the pregnancy in this case did not prevent a mental attack.

CASE 3.—A married woman, aged 20, had been under antepartum care at the Sloane Hospital from January to June, at which latter time she began to show albumin in the urine and hypertension. She was hospitalized there in July and delivered of a macerated fetus a month later. Two days before the delivery delusions and hallucinations developed. She was shortly admitted to the Psychiatric Institute. The albumin and casts in the urine and the hypertension gradually disappeared; she cleared mentally and was discharged within two months as recovered. About nine months later she again reported at Sloane Clinic in a pregnant condition. I advised against abortion. The patient had an uneventful pregnancy and labor with a healthy child and was recently discharged from the maternity hospital.

CASE 4.—An unmarried woman, aged 21, had been treated for diabetes for four years in the medical clinic. She did not adhere closely to the prescribed diet and at times had severe insulin shocks. After seeing a maternity moving picture she became confused and the next day was admitted to the Presbyterian Hospital in coma. Under treatment she was confused, unstable, and at times catatonic. She was admitted to the Psychiatric Institute with a blood sugar of 375 mg. and the urine showed 9 per cent sugar, acetone and diacetic acid. The diabetes was controlled, her mental symptoms cleared up and she was discharged as recovered after four and a half months. Within a few months she became pregnant and was married. I advised against abortion from the psychiatric standpoint. She went through pregnancy and labor without mental symptoms and has a living child.

CASE 5.—A married woman, aged 24, attempted suicide with gas when she found she was pregnant. As a result of the gas poisoning a mental disturbance developed, with excitement, clouding of the sensorium and amnesia, and she was committed to a state hospital. The pregnancy was not interrupted. She was discharged after three months' residence when seven months pregnant and went through an uneventful later pregnancy and labor with a normal child. She still showed lapses of memory and difficulty in concentration and this condition has continued approximately for a year since the childbirth, the late effects, I believe, of the gas poisoning. She is in good

6. Robinson, A. L.: Effect of Reproduction upon Insanity, *J. Obst. & Gynaec. Brit. Emp.* 40:1 (Feb.) 1933.

general physical condition. One cannot conclude that she was harmed by the lack of interruption of pregnancy.

CASE 6.—An unstable woman, aged 24, unhappily married, had an induced abortion which was followed by a depression from which she recovered. At the age of 33 she passed through childbirth but six months later psychoneurotic symptoms became accentuated. Shortly after this she became pregnant again and had an induced abortion. A fourth pregnancy ensued during which she showed psychoneurotic symptoms and was admitted to a private sanitarium, where she remained for about four months. On her return home, however, her symptoms became aggravated. It was recognized at the Sloane Antenatal Clinic that she had a psychiatric condition; because of her difficult home situation it was not considered advisable for her to remain at home, and she was admitted to the Psychiatric Institute, where she remained through the latter months of her pregnancy. She was in the first stages of labor when she was transferred to the Sloane Hospital, where she had a normal childbirth. Her instability made it impossible for her to live at home for any length of time and she was not satisfied to stay away from her home, so that she was again admitted to the institute seven months after childbirth. She was more settled, apart from her husband. Within a few months she became enthusiastic about returning home and caring for her family. The patient's children appear to be healthy and normal. It appears to have made little difference in this woman's mental condition whether abortion was induced or whether she was allowed to go through with the pregnancy.

CONCLUSIONS

1. There appears to be no individual neurologic or psychiatric disorder that is an absolute indication for abortion in women suffering from such disorders.

2. Experience shows that some women with severe advanced neurologic disorders may go through pregnancy and have healthy children.

3. Experience shows that some women suffering from severe mental diseases may pass through normal pregnancy and childbirth.

4. Experience shows that abortion does not necessarily prevent a recurrence of mental attacks or bring about recovery from attacks already existent. The pregnant woman's general physical condition must be given careful consideration in a decision regarding the termination of pregnancy.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRs. PARDEE, HERRICK, POTTENGER,
WAGENER AND CHENY

DR. FREDERICK J. TAUSSIG, St. Louis: In setting the indications for therapeutic abortion, one should be guided not merely by the question of the disease and the extent of its involvement but by the question of the individual patient having that disease. What is her age, the number of her children, her economic status as it affects her diet, her household and parental obligations, her ability to carry out rest or institutional treatment, the hereditary and constitutional factors in the particular case? To say that if the indications are not made hard and fast it leaves the door open to all kinds of abuses may to some extent be true, but all know that these abuses exist. Unscrupulous physicians readily find excuses for an abortion that is really done for other reasons. That is no reason for taking away from the conscientious physician the privilege of deciding each case on its own merits with that broader wisdom which seeks to act for the good health, happiness and proper care of that particular family. In the last two decades the indications for therapeutic abortion have shown a decided change. The number of cases that must be aborted have taken a definite drop, while the number of cases that may be aborted have at the same time increased. On the one hand improvement in the treatment of hyperemesis, the striking

results obtained by the sanatorium treatment of tuberculosis, more dexterous management of cardiac and nephritic mothers, and the diminishing mortality attending cesarean section for contracted pelvis have almost cut in half the number of patients who had to be subjected to therapeutic abortion ten to twenty years ago as a life-saving procedure. On the other hand, many mothers with ailments much less serious than these were brought to an early grave or seriously handicapped for life because of factors that were beyond their control, such as poverty, undernourishment, overwork, overworry, an asthenic constitution and a bad heredity. More of these women are now being subjected to a therapeutic abortion if they have such a physical ailment. That a therapeutic abortion is not a minor operation must again be emphasized. It has a mortality even in expert hands which equals that of a simple laparotomy, and a morbidity that is greater than that of such an operation. Its sequelae in the form of minor pelvic infections, endocrine disturbances and psychic upsets are very common, as has been amply verified by the voluminous reports in recent years from Russian sources. May I emphasize also the advisability of prompt decisions in setting the indications for a therapeutic abortion. Delay increases the risks and lessens the benefits to the patient. An abortion done before the eighth week of gestation is half as serious a procedure as one done between the third and sixth months.

DR. JOSEPH B. DE LEE, Chicago: The reason the first part of this session was made a symposium was mainly personal. I myself wanted to know what men in the various specialties did in cases of pregnant women who had various nonobstetric complications. I often get letters from doctors asking me whether an abortion should or should not be done in a given case. One inquires whether a woman who has had a resection of six feet of small bowel and who is pregnant six or eight weeks should have an abortion done. An inquiry is made regarding a woman having a progressive otosclerosis and whose sister and aunt are deaf. Should an abortion be induced? A doctor reports a case of a woman who has a spleen so large that it rests in the left iliac fossa. She is pregnant six weeks. Should an abortion be induced? Another doctor reports a case of a woman with a skin disease covering her entire body and becoming worse during pregnancy. He does not know the nature of the skin disease. What should be done in the case of a woman with tuberculosis of the left kidney and pregnancy? The kidney was removed. Should an abortion be done? Inquiries come as to whether an abortion should be performed for leukemia, for Hodgkin's disease, and for thrombocytopenia. Should an abortion be performed for chorea which occurred in childhood and became worse following pregnancy? With the present unmorality of the times, the induction of abortion is adopted without any compunction and the purely scientific side of the subject has been stressed. Dr. Adair touched on the social side and possibly the religious side; I have tried, however, to keep that out of the discussion so as to prevent any real discussion. I have a letter on my desk asking for advice in this case and I hope the neurologists can enlighten me: A grandmother developed epilepsy at the age of 45 and died at 60. She had two children, a daughter and a son. The son became insane at 52 and committed suicide at 55. The daughter had three children. One son developed epilepsy at the age of 20 and now has suicidal tendencies. The two girls are married. One is three months pregnant and one is six months pregnant. The woman who is six months pregnant is not alarmed; she is willing to go through pregnancy. The woman who is three months pregnant is fearful that her child will develop epilepsy. The doctor asks about abortion. When I get home, I am going to tell this doctor what I am being told here today. I feel that it is very important for the general practitioner to know what to do in unusual cases in which an abortion is requested.

DR. MISCH CASPER, Louisville, Ky.: I wish to make a plea for the unborn child. It obviously cannot talk for itself. This subject is a scientific one, but on the other hand it goes contrary to the teachings of Christianity, which has dominated the civilized world for twenty centuries. I take it that the age of the fetus has very little to do with the killing of it. Its life is just as important to it at one month as it is at nine

months, the relativity being about the same as a child of 1 year to that of a child of 9 years, were one considering its destruction. But when some of these indications for therapeutic abortions are considered and I wish to say that I never have knowingly committed a therapeutic abortion—there is always a way to avoid it. Pernicious vomiting can now be controlled with treatment. Largely that is true of hypertension and even of severe heart cases. Who knows what minute a patient with severe heart trouble is going to die? I tell the patients that they may die the next minute or any minute of any day or any night. Who can say how much if any greater danger exists by going on to viability? The great question is, Can both be saved? I think scientific men should more diligently apply themselves to the task of trying to save both mother and child. Then this problem will resolve itself into the attitude of the physician toward the moral side of it. He can do a great deal. Some of us do not hesitate to advocate a therapeutic abortion because that is the easiest way out. I am glad to hear the lung specialist say that the pendulum has changed in pulmonary tuberculosis in the last twenty-five years and the psychiatrist that there is no essential indication for therapeutic abortion in psychiatry.

DR. CLARENCE O. CHENEY, New York: Review of the literature shows that seventeen of twenty-three experts were in favor of abortion in severe cases of chorea, particularly when threatened cardiac symptoms or psychotic symptoms of a marked degree were present. Regarding the question of abortion in the family that was mentioned and about which an inquiry was made, I was not able to follow the relationship throughout, but I would say that an abortion was not necessarily indicated. Before one can form a definite idea of the prospects of the child that might be born to the woman mentioned, one would wish to know about the family history and the stock of the father, because the father has just as much a bearing on the type of child as the mother. I do not see any definite indication for abortion in the history of the mother.

DR. HENRY P. WAGENER, Rochester, Minn.: I included a short reference to retinitis pigmentosa in my unabridged paper. The question of retinitis pigmentosa in pregnancy is more one of eugenics and sterilization than of therapeutic abortion. I think that it must be realized that a great many of these patients with hereditary retinitis pigmentosa are from families who have various other hereditary defects, among them being epilepsy and nerve deafness. As far as the patient herself who has the retinitis pigmentosa is concerned, I do not believe that under the ordinary conditions of a well conducted pregnancy there is much danger to her sight. During pregnancies in which undernourishment is a marked feature, night blindness of the idiopathic type can develop without retinitis pigmentosa. This type of night blindness can be readily controlled by the addition of proper food, particularly the proper amount of vitamin A, to the diet, and usually disappears promptly after delivery even if the vitamin A has not been sufficiently added during the pregnancy. I have recently observed the effect of pregnancy on a patient with retinitis pigmentosa. During the later months of the pregnancy, when presumably nutrition was somewhat reduced and the stock of vitamin A in the tissues was somewhat depleted, there was a definite progression of the visual defect. However, after the termination of pregnancy at term, there was a very rapid return of vision. The diminution in vision that may occur in these cases of retinitis pigmentosa during pregnancy is probably due to the extra call on the vitamin A sources of the mother. A few more words might be said with reference to the occurrence of retinitis and detachment of the retina in cases with hypertension. It is true that at the present time, under proper conservative methods of control of hypertensive disease, fewer patients than formerly show a tendency to develop angiospastic retinitis. In the cases of primary retinal detachment which are not associated with or the result of retinitis, abortion is indicated largely for the preservation of vision; for in this type of case, after the termination of pregnancy the vascular system often returns completely to normal as far as can be told by clinical and laboratory tests, and these patients can often go through later pregnancies without complications.

DR. W. W. HERRICK, New York: Any degree of hypertension, any impairment of the ability of the kidney to pass a concentrated urine, any degree of albuminuria, or of nitrogen retention, is an indication for an abortion. The question of procedure in cardiovascular-renal disorders seems to me to become increasingly clear and I think it has been somewhat clarified this afternoon. The pure nephroses are rare indeed and when they occur in pregnancy probably are complicating factors in a vascular condition, so they require no separate discussion. I agree with Dr. Mussey that the pure nephritides are relatively rare. They constitute about 10 per cent of the 1,000 cases of toxemia that are at present under study in the follow-up clinic of the Sloane Hospital. When nephritis declares itself early in pregnancy and does not yield to treatment, abortion should be performed. If it does not declare itself until late in pregnancy or if it does not progress seriously, one may attempt to carry on to the period of viability or to term. It is of great interest to me that the ideas that I have entertained for the last fifteen years as a result of the study of toxemias of pregnancy seem to be accepted elsewhere. The evidence from the studies of cases of toxemia, the studies of retinal circulation, of the capillary circulation in the nail fold, the follow-up studies, and now the necropsy studies which are appearing, seem to indicate definitely that the larger group of toxemias of pregnancy comprising preeclampsia and that great group of mild toxemia in which the dominant symptom is hypertension are widespread vascular disorders that have as an end result an arteriosclerosis not only in the kidney, sometimes not in the kidney at all, but in one or two of the necropsy cases in other parts of the vascular tree. These are not emergencies except the acute eclampsia, and they had probably at best be left to nature. In the early stages of pregnancy the hypertensive cardiovascular disease usually suggests the desirability of abortion, particularly if it does not yield to treatment. In the late stages, if it is not complicated by serious retinitis, albuminuria, edema, decline or other evidences of grave disturbance, one can attempt to carry on to viability or to term. I believe it important and less confusing to give up the traditional term nephritis as applied to renal complications of this vascular disease. I would suggest the use of the term "vascular type of toxemia" for this predominant group.

DR. HAROLD E. B. PARDEE, New York: I believe that Dr. Hamilton sizes up his patients much as has been suggested in this paper, although he may not consciously place them in any definitely named functional categories. I believe that he so rates them in his mind and I believe this because his results, his statistics, are so good. I cannot agree, however, with his statement that "any of these patients may develop cardiac failure; that they may in the morning appear to be all right and in the afternoon develop severe cardiac failure." Such things do not happen unexpectedly when the functional grouping is used. I refer to table 2, which shows 157 patients in class 1, all with what Dr. Hamilton would call serious cardiac disease, and none of these patients died. In class 1 and class 2A combined there were 337 patients with serious cardiac disease and in this group only one patient died. This death was the result of embolism of the popliteal artery. In contrast with these figures are 209 patients in class 2B and class 3, of whom twenty-four died, or 12 per cent. I believe that any classification which can select 337 patients as in a good category and show a mortality of 0.3 per cent and can select 209 patients as in a dangerous category and show a mortality of 12 per cent in this group is a useful classification and should be helpful in the management of these patients during pregnancy.

DR. F. M. POTTINGER, Monrovia, Calif.: In answer to the question that the chairman asked about tuberculosis of the kidney, I wish to say that if I had a patient in whom a kidney had been removed because of tuberculosis, but the patient was otherwise well, I would see no reason for an abortion. If, on the other hand, the patient had a kidney that was actively tuberculous and the disease was spreading, or the disease was so active that the patient was suffering from an elevation of temperature at the time, I certainly would advise abortion if the pregnancy was discovered in the early months and would advise considering it even if the pregnancy was further advanced.

OBLITERATIVE VASCULAR DISEASE

PRELIMINARY REPORT ON TREATMENT BY
ALTERNATING NEGATIVE AND
POSITIVE PRESSUREGÉZA DE TAKÁTS, M.D.
CHICAGO

Obliterative vascular disease is characterized by a sudden organic occlusion or a gradual narrowing of the arterial tree. The viability of the affected part or organ will depend on the rapidity with which a collateral circulation can be established. In studying the methods that nature utilizes to effect the maintenance of a sufficient circulation, one may observe that blood pressure usually rises above an arterial obstruction, thereby forcing blood more readily into the preformed but unused channels. This presupposes an adequate myocardial reserve. Should this be low, as in arteriosclerosis with hypotension, a support of the blood pressure with digitalis or ephedrine is helpful.¹ Secondly, the peripheral vascular bed enlarges, an effect designated by Bier "blood thirst" of the tissues and probably due to the accumulation of metabolites in the isehemic or anemic area. This peripheral vasodilatation may be supported and augmented by drugs, notably theobromine,² and by continuous, though not excessive, heat. The difficulty, however, with organic vascular disease is that in its late or terminal stages, when seen by the physician, the capacity for vasodilatation is small or completely abolished. This failure of the vascular bed to dilate in times of increased load or in a sudden vascular occlusion has often been the immediate cause of the death of the tissues.

It was a significant suggestion then, made simultaneously by two groups of investigators,³ to increase the peripheral blood flow to the extremities by encasing them in air-tight compartments made of aluminum or pyrex glass and subjecting them to the alternate effects of suction and positive pressure, thus creating, in the words of Reid, a "peripheral heart apparatus." The pressures used by Landis and Gibbon were from 80 to 120 mm. of negative pressure for twenty-five seconds, and positive pressure of from 60 to 80 mm. for five seconds, whereas Herrmann's apparatus, in its perfected stage, was intended to create 80 mm. of negative and 20 mm. of positive pressure, alternating at cycles from two to four a minute. The previous literature on the use of negative pressure to stimulate blood flow need not be considered here;⁴ the principle of alternating the pressures, and alternating them at short intervals, is a radical departure from the previously used continuous suction with occasional release.⁵

THEORETICAL CONSIDERATIONS

Landis³ pointed out that the law of Poiseuille is applicable in the presence of rigid arteries incapable of dilatation. Early in the last century Poiseuille observed that the amount of blood flowing through a rigid tube depends on the fall in pressure along the tube. As a continuous elevation of the systemic blood pressure may seldom be accomplished, the diminution of venous pressure, which increases the difference between capillary and venous pressure, may more effectively augment blood flow through the capillary bed. This law was applicable with restrictions to capillary circulation.⁶ Landis and Gibbon also showed in normal subjects, under controlled temperature conditions, that blood flow as indicated by skin temperature was greater in the limb exposed to variations in pressure. It is easily demonstrable through a glass boot that during suction the skin becomes red as the capillaries and veins are filled with blood, whereas under positive pressure, which is used to empty the peripheral vascular bed, the skin blanches. "The emptying affords a reservoir in which fresh arterial blood may be drawn by the next period of negative pressure."

PRACTICAL APPLICATION

While Landis and Gibbon presented these theoretical considerations and described a few clinical cases, Reid and Herrmann, independently from these workers, tested the idea of alternate suction and pressure in a mass experiment. In 1932 Herrmann designed and built a machine, which during construction had undergone several modifications. Publication was withheld until more than 3,000 treatments were given. In his Matas lecture in New Orleans, Reid reported that sixty-nine patients received more than 5,500 treatments of this "passive vascular exercise." In a vast material, observed under conditions in that most of these patients were hospitalized, commands the greatest respect, and their conclusions must be of general interest to all interested in this form of treatment. They also found, as Landis, that the skin temperature rose during treatment. It stayed higher and gradually returned to its previous level in two days. From this they concluded that treatments might be given in the chronic form of obliterative disease about three times a week for periods of one-half hour, whereas, in acute vascular occlusions, treatments as often as from five to seven times a day were recommended. Reid carefully summed up the conclusions at New Orleans by saying that the treatment has been much the most effective single stimulant to the development of collateral circulation. For critical periods of vascular disease it saved many limbs that would otherwise have been amputated. It has also been used to save the life of an extremity following the ligation of a large artery. It has been used in chronic arthritis to increase the circulation.

In his latest article, Landis studied sixteen patients very carefully, in regard to changes in skin temperature, color and the effect on rest pain, on the healing of indolent ulcers and on frank gangrene. Concerning the real therapeutic value of the procedure, he was unwilling to state whether the development of collateral circulation can permanently return the tissues to a normal state. He showed, however, that patients might be tided over acute crises of rest pain and ulceration, so that time might be gained for the natural development.

6. Landis, E. M.: Poiseuille's Law and Capillary Circulation, *Am. J. Physiol.* 103:432 (Feb.) 1933.

of improved circulation. Shipley⁷ treated seventeen patients with different types of vascular disease and included cases of ununited fracture and causalgia. He noted a marked improvement of circulation in all of them.

Herrmann and Reid attempted a closer evaluation of the results obtained on 300 patients with more than 12,000 treatments. They emphasized that in the acute forms of peripheral obstruction, such as thrombosis or embolism, trauma or arterial ligation, the results are truly startling. But when they were dealing with a slow, progressive arteriolar obstruction, the results were not nearly so encouraging; in fact, 42 per cent of the cases were not benefited. Between these two extremes of acute arterial obstruction and the slow progressive arteriolar disease, all variations in the rate of progression of the disease are found and this naturally reflects on the value of the pressure therapy. Reid⁸ emphasized in his most recent paper, read before the New York Academy of Medicine, Nov. 14, 1934, that gangrene and infection of the foot call for excellent surgical judgment in the use of the alternating pressure.

OWN OBSERVATIONS

Treatment was begun at the end of April 1934 with the "pavaex" apparatus of Herrmann. Every patient received a systematic examination of the peripheral vascular status, which included the palpation of pulses, the cutaneous histamine test, the oscillometric curves at different levels and, in doubtful cases, an estimation of the capacity for vasodilatation.⁹ This was determined by a peripheral nerve block¹⁰ and in the later cases by the simple and excellent method of Landis and Gibbon.¹¹ Only organic types of vascular disease showing little or no spasm were selected, as suggested by the originators of the method. For estimation of the improvement, the claudication, rest pain, cyanosis and the increase in the oscillometric curve were studied.

GROUP 1.—Arteriosclerosis Obliterans.—The average plan of treatment was, as originally outlined by Reid and Herrmann, to administer treatment three times a week for half an hour. Better results seem to be obtained by daily treatment for an hour. All these patients were ambulatory, most of them dispensary patients, coming from a long distance. Four stayed away because of no improvement after six treatments. Six patients received from fifty to a hundred treatments; all these noted subjective improvement. It became obvious that objective improvement could be registered only after two weeks of intensive treatment, and that forty or fifty hours of treatment should possibly be given for a real trial of the method. For some of these older patients, one of whom was 78, the other 80 years old, a daily trip to the outpatient department was exhausting. Their cardiovascular status was poor; two were fibrillating, another was decompensated.

The best results were obtained in a man, aged 64, with hypertension, auricular fibrillation and an indolent ulcer, who took fifty one hour periods of treatment. The ulcer became painless and showed a marked

tendency to heal. Another man, aged 61, took sixteen half hour and twenty-nine one hour periods, with definite objective improvement. My experience with this group as a whole is that daily periods of one hour should be insisted on, and that unless they are hospitalized a number of them will stay away for various reasons and will not derive benefit from a few treatments.

GROUP 2.—Acute Vascular Occlusions (thrombosis, embolism).—Four patients were treated in this group. They received almost continuous treatment, one hour on and one hour off, through forty-eight to seventy-two hours. One 78 year old man who showed a popliteal embolus following prostatectomy was seen only two days after the occlusion had to be amputated above the knee and died of a pulmonary embolus after the operation. A girl, aged 16, with a *Streptococcus viridans* endocarditis, was brought in forty-eight hours after an embolism occluding both iliac arteries, chiefly the right, on which side a gangrene of the first three toes set in. This patient received sixteen three hour treatments. The gangrene did not progress, but neither did it appear on the untreated other side, which was pulseless from the popliteal space down. She died of a cerebral embolism. One man, aged 72, with peripheral arteriosclerosis and a failing heart, developed a popliteal thrombosis. He received twenty-six half hour treatments, did not improve, was discharged home and died there suddenly. One man, aged 56, was shot through the popliteal fossa, with the production of a traumatic thrombosis of the popliteal artery. He was treated one year after the injury because of intermittent claudication, numbness and coldness in the toes. After twenty-six one hour treatments he felt no improvement, although there was a slightly increased capacity for vasodilatation. The case was regarded as one of compensation neurosis.

My experience with this group was very limited. The general conditions of these patients, their tendency to repeated and multiple emboli, and the fact that none of them were treated the first six to eight hours following the embolism, led to complete failure to avert amputation or death. The fourth case, which properly does not belong here, had a medicolegal aspect, which makes an evaluation of the results especially difficult.

It would be unfair, however, to condemn the method in this group of cases, which seem to give the most startling results in the experience of Reid and Herrmann. As is the case with the results of embolectomy, the education of the medical profession to regard these cases as a true surgical emergency and admit them to the hospital during the first few hours after the acute occlusion has occurred would be the greatest single factor in saving the limb.

GROUP 3.—Thrombo-Angiitis Obliterans.—Two cases were selected, because they showed very little spasm and no evidence of a recent activation. One man, aged 51, received fifty-two one hour treatments. There was no subjective or objective improvement. He had symptoms of a more generalized vascular involvement (coronaries, mesenteric vessels), and complete rest, abstinence from tobacco, and sufficient fluid intake were instituted. His general condition remained unimproved. Another man, aged 49, received twenty-five half hour treatments with no results. He later improved on sub-reactionary doses of typhoid vaccine.¹²

12. de Takáts, Géza: Peripheral Vascular Disease, to be published.

When one realizes how slight an injury, how trivial a respiratory infection is capable of activating a migrating phlebitis or arteritis in these patients, the danger of subjecting patients with true Buerger's disease to such powerful vascular massage is obvious. In the terminal, healed stages of obliteration, a cautious treatment in two cases did not seem to bring about improvement.

GROUP 4.—Endarteritis Obliterans.—This group, strictly separated from Buerger's disease, is the obliterative healed stage of many different chemical and bacterial injuries that affect the intima. For purposes of discussion I have grouped the frost bites, the syphilitic, tuberculous arteritides, the scleroses due to lead and arsenic, into this group.¹²

One man, aged 33, with considerable focal infection and rheumatoid joints, had a marked vascular occlusion. Following six treatments, his intermittent claudication

Fig. 1.—Oscillometric curves of J. F., a man, aged 53, with peripheral arteriosclerosis: solid lines, oscillometric curve at the ankles; interrupted lines, oscillometric curves at the mid thigh. Note the small elevation of the curve at the right ankle. The foot clinically was pulseless. Note the unusual height of the curve at mid thigh, compared with that of the left side. This patient is pounding blood into the extremity with vascular obstruction below the knee.

was greatly improved. Another patient, aged 43, had thirty-five one hour treatments in the hospital. He had a phlebitis of the retinal vessels, suggestive of tuberculosis, and a marked obliterative vascular disease in both lower extremities, with absence of calcification. No biopsy was permitted. He was hospitalized for two weeks. The claudication improved from one to six blocks. However, after discharge from the hospital, although receiving ambulatory treatment once a week, he relapsed into his previous condition. One man, aged 41, suffering from a severe frost bite suffered two years previously, and an indolent ulcer on the great toe, showed a rapid healing of the ulcer. A skin graft took well. He received fifty-eight half hour treatments. Another man, J. H., aged 46, with a rheumatic heart, arthritis of the foot, fallen arches and a history of prolonged exposure to cold, showed a marked improvement in color and capillary circulation. The joint pains were not influenced.

In this group there was a marked improvement in all cases, which is due, I believe, to the fact that, first, this is a younger age group; second, the interference with circulation is in the small arteries and the larger vessels are free, and, third, with the exception of one case, prolonged treatment was given.

THE CLINICAL ESTIMATION OF IMPROVEMENT

1. Rest Pain.—All patients afflicted with rest pain, which is particularly excruciating in acute vascular occlusion, were promptly relieved during the application of alternating pressures. The patient with the popliteal embolus went to sleep under the treatment, without sedatives. The rest pain returns, however, when the apparatus is stopped. The difficulties encountered in maintaining continuous treatment for long periods of time will be discussed later.

2. Intermittent Claudication.—This is the complaint which brings most of the chronic obliterative vascular obstructions to the attention of the physician. In the arteriosclerotic group, claudication improved in four out of the ten patients. These few were patients who took the most treatments, who belonged to the younger group and whose general cardiovascular status was fair. The slightest improvement was from one to three blocks, the greatest from one-half block to eight blocks. Obviously, so many factors enter here that such records serve only to encourage the patient and are not regarded as an accurate, although a very suggestive, indication of better circulation. In the group with Buerger's disease, no improvement was noted, while in the group diagnosed as endarteritis obliterans, claudication improved from one to six blocks, from one-half to eight blocks, from six blocks to a mile, and from six blocks to no cramping at all.

3. Color Changes.—Cyanosis often is seen to disappear during treatment. This was particularly true in the case of frost bites, although the climatic and meteorological conditions are naturally important. That patients are apt to get more benefit from this treatment when maximal vasodilatation enlarges the reservoir capacity of the vascular bed has been emphasized by Landis, who advises an electric pad or immersion into hot water for the upper extremities, to produce reflex vasodilatation during treatment.

4. The Oscillometric Curves.—All patients had an oscillometric examination before and during treatment. From these curves, which will not be reproduced here for lack of space, I learned that a high blood pressure, and particularly a higher curve on the affected side above the obstruction, gives a good prognosis as to the efficacy of treatment (chart 1). This is one of the mechanisms of developing collateral circulation. Unfortunately, however, many of the older patients with arteriosclerosis have a low, plateau form of curve above the knees, or no oscillations at all. This is especially true of the acute vascular occlusions, emboli occurring at the iliac bifurcation, or at the aorta. Suction of blood from a relatively avascular area cannot be as helpful as when the main vessel above the cuff of the machine is pulsating and widely patent. In one case it was possible to improve this flat oscillometric curve (chart 2). In general, however, it was impossible to see definite changes in the curves. This is not surprising, as the improvement of circulation is probably in the nonpulsatile element of collateral circulation.¹³

13. Dr. R. W. McNairy is responsible for the distinction between pulsatile and nonpulsatile circulation. This is a very expressive term.

5. *The Healing of Ulcers.*—As stated later, the indolent ulcers due to endarteritic processes heal faster and become painless. The efficacy of treatment will depend almost entirely on the capacity of the peripheral bed to dilate, and a sufficient myocardial reserve to maintain head pressure.

6. *The Effect on Frank Gangrene.*—In the cases that were admitted with frank gangrene, amputation had to be performed, except in the case of the girl with septic endocarditis, in whom amputation was considered useless. The question arises whether the level of amputation could be changed to a lower site following treatment.

In most of the acute occlusions there will not be enough time to establish a new collateral circulation. The effect, then, must be due to a release of spasm in the collateral vessels, a fact that has also been suggested by Reid.⁸ My observations with the intravenous use of papavcrine in acute vascular occlusions would indicate the importance of relieving the initial spasm of collaterals in acute vascular occlusions.¹⁴ The last indication of a spreading infection would require stopping the treatment and amputation. In one case it was possible to obtain positive histamine flare at the level of the knee joint, whereas, two days before, the first positive reaction was obtained at midhigh.¹⁵ Outside of infection, the increase of venous thrombosis should also militate against further vascular exercises.

CONTRAINDICATIONS TO TREATMENT

On theoretical grounds, infection and venous thrombosis, appearing separately or jointly, should constitute a serious warning against the use of the machine. Particularly in the infectious type of diabetic gangrene with osteomyelitis of the toe, it would seem unwise to use negative pressure. McKittrick and Root¹⁶ pointed out the frequency of a latent streptococcic septicemia in diabetic gangrene. Venous thrombosis in the larger vessels often accompanies arterial obstruction. A recent soft clot may readily be mobilized by this treatment. One should also think of certain acute venous thromboses, which produce a temporary arterial spasm and exhibit cold, cyanotic, numb and tingling toes and may mislead the surgeon to apply the apparatus for an arterial embolus. The differential diagnosis of an arterial embolus, arterial thrombosis and venous thrombosis is important for those using the machine.

DIFFICULTIES OF TREATMENT

1. The apparatus is not noiseless. In using it for a long period for acute occlusions, not only the patient but even more his neighbors are greatly handicapped or inconvenienced. This necessitates a private room for such patients, or the placing of the apparatus in an adjoining room.

2. The rubber cuff connecting the glass boot with the extremity under treatment is supposed to be soft and adjustable, not causing any venous constriction. Up to the present no cuff has been suggested or supplied that would maintain the partial vacuum and not produce constriction of the limb. This constriction is so uncomfortable that patients will not stand the treatment for longer than an hour; some of them complain bitterly after half an hour. It is obvious that this steady venous hyperemia militates against the full effects of alternate

suction and pressure. It favors venous stagnation and may predispose to venous thrombosis. The latter is merely a theoretical consideration, as I have not observed any such effect.¹⁷

3. The glass boot is so constructed that it will encase the extremity above the knee. Reid and Herrmann pointed out the importance of the external and internal geniculate arteries as collateral channels. But many of these patients have arterial obstruction much higher than midhigh. For these with flat or absent oscillometric curves at that level the suction cannot be very effective.

COMMENT

This preliminary report is obviously based on such a small number of cases, treated and followed for such a short period of time, that its only justification lies in the importance of outlining the present status of this therapy. It is not possible at this time to state the scope and the lasting efficacy of this treatment. The facts that speak in favor of this treatment can be briefly enumerated. First, I believe it is correct to assume that a temporary increase in blood flow can be obtained in the presence of an organic obstruction and in the presence of a peripheral vascular bed, which can hardly dilate, even if deprived of its vasoconstrictor tone.

Fig. 2.—Circulatory record of L. K., aged 57, before and after fifty-two hours of treatment: square blocks after fifty-two hours of treatment. While the curves at the ankle remained unchanged, the curves at the midhigh were definitely improved. Note how straight these curves are, indicating the rigidity of the vessels.

Second, it would seem that, if these treatments are given often enough, at least an hour a day for periods of weeks and months, a subjective and objective improvement may be obtained in patients for whom no other therapy except amputation is available. It is obvious that with increasing experience certain groups will be eliminated and others especially singled out for this treatment. Third, if used by men familiar with peripheral vascular disease, no harm can come from its use. On the contrary, certain acute vascular occlusions, if subjected as early as six or eight hours after the occurrence of typical clinical symptoms, may be actually tided over the crisis with minimal loss of tissue.

Against the success of this treatment militate the following factors: First, one is dealing here with some patients who have arrived to a terminal stage of a generalized cardiovascular disorder. If their myocardial reserve is gone, if their aorta and large vessels keep sending more and more intimal plaques to obstruct the peripheral vessels, if their minute vessels are gradually closing up, and if their general reaction to injury and repair are at a low ebb, a temporary aspiration of blood

17. At present a long segment of a seven inch inner tube is used as a cuff. This tube had to be split by vulcanizing a strip of rubber tissue into it, to enlarge the circumference.

into the periphery can hardly be of lasting benefit. These patients would probably respond much better if they were hospitalized. As pointed out by Reid, the passive vascular exercise brings new blood to the part but without any additional requirement of oxygen consumption, whereas active exercise, walking and so on, uses up the small reserve of blood for metabolic activities. It is also obvious, and has been emphasized throughout the writings of Reid and Herrmann, that the method is only a valuable adjunct to other forms of conservative therapy and has not been put forward as a cure-all. In the embolic group, the source of the embolus may continue to send showers into the other extremity and into vital organs. Nor do all these patients arrive as early to the surgeon as they should. The practicing physicians can hardly take the blame when the interns of some of the best hospitals fail to recognize or to act on the presence of a peripheral embolus.

Second, the method is not perfected to the stage at which the treatment can be continuous for hours or days. The prolonged pressure of the cuff is painful and probably not harmless. The continuous throbbing of the machine is inconvenient. More important, if suction could be instituted from a higher level, such as around the waistline, and patients encased in light sleeping bags with a metal framework to stand the variations in pressure, an inflow of blood could be secured for the type of extremity that is pulseless at the femoral ring.

From the brief analysis of these factors that speak for and militate against the success of this treatment, it can readily be seen that the younger individuals, with less degree of cardiac damage, and those whose obstruction is at or below the popliteal fossa, will derive the most benefit. Especially suitable seem patients with localized forms of endarteritis, as in frost bite, whose cardiovascular apparatus is not damaged or is only moderately damaged. In the hands of those who will select their patients with as much care as they would in selecting them for a major operation, the method can do no harm and may show spectacular results. For the cardiovascular wrecks, and the embolic patients, arriving with a forty-eight hour old frank gangrene, the apparatus should not offer any hope. No attempt has been made as yet to treat the purely spastic types of vascular occlusion.

As to the permanent improvement following a temporary restoration of circulation, nothing can be said; nor in my opinion will a mass of joint statistics be of any avail. The original course of the disease will prevail and only individual prognoses can be made.

SUMMARY

1. The principle of treating organic vascular obstructions by an intermittent negative pressure environment is physiologically sound.
2. The apparatus of Herrmann, delivering 80 mm. of negative and 20 mm. of positive pressure, was used on twenty patients. Ten of them had arteriosclerosis, four suffered from acute emboli or thrombosis, two were afflicted with Buerger's disease, and four had endarteritis obliterans.
3. The improvement was gaged in regard to rest pain, intermittent claudication, changes in color, changes in the oscillometric curve, the healing of ulcers and the effect on frank gangrene.
4. Rest pain was promptly abolished with the beginning of the treatment. Intermittent claudication

was improved in some of the cases, chiefly those in which there was sufficient cardiac reserve and which were treated long enough. Cyanosis improved, particularly in the frost bites. The oscillometric curve of the total group did not change, except in one instance. Indolent ulcers healed more promptly. In the stage of frank gangrene, amputation became necessary.

5. Most favorable seemed to be the cases presenting involvement of the smaller vessels and relatively less cardiovascular damage. This seems to be at variance with the experience of Reid and Herrmann. Least favorable were the hypotensive arteriosclerotic patients with cardiac damage and flat or absent oscillometric curves at midthigh. The acute vascular obstructions all came too late for treatment. Two cases of Buerger's disease showed no response. The endarteritic patients were generally benefited.

6. The apparatus requires technical modifications, so that it can be used for a longer period of time, that it be noiseless and that it may encase larger areas of the extremities.

7. At present the method should be under the control of peripheral vascular clinics with facilities of hospitalization, careful selection of cases and evaluation of results. The therapy is a valuable adjunct to other useful methods already in use. Late results cannot be predicted. They will be mainly governed by the underlying cause and progressive tendency of the vascular occlusion.

A STUDY OF ONE HUNDRED CASES OF JAUNDICE

WITH PARTICULAR REFERENCE TO
GALACTOSE TOLERANCE

LEON SCHIFF, M.D.

AND

FANNY A. SENIOR
CINCINNATI

During the last three years we have studied a group of 100 patients with jaundice at the Cincinnati General Hospital with particular attention to clinical manifestations, galactose tolerance and ability to excrete bromsulphalein. We have determined the degree of jaundice during the course of illness by means of the icteric index and van den Bergh determinations and the presence or absence of complete obstruction by study of duodenal contents, urine and stools. We are thoroughly in accord with the importance of clinical observations in the differential diagnosis of jaundice as recently stressed by Flood, Seegal, Spock and Loeb.¹ We feel, however, that laboratory studies, particularly the galactose tolerance test, may prove of great help in the diagnosis of some cases and lend confirmatory evidence in others.

The galactose tolerance test was devised by Bauer² in 1906 as a test of hepatic function. Two years later

From the Department of Internal Medicine, University of Cincinnati College of Medicine and the Medical Service, Cincinnati General Hospital. Read before the Section on Pathology and Physiology at the Eighty-Fifth Annual Session of the American Medical Association, Cleveland, June 14, 1934.

used extensively in European clinics but it is only recently that clinical application of it has been made in this country. This has been due largely to the work

3 Bauer, R. Ueber alimentäre Galaktosurie bei Ikterus, Deutsche med Wchnschr 24:1505, 1908

of Shay and Schloss,⁴ who have corroborated Bauer's results and have emphasized the importance of the test in the differential diagnosis of painless jaundice, particularly that appearing in the later decades of life. For an excellent review of the literature on the subject of this test, the reader is referred to the papers of Shay, Schloss and their associates and to the more recent publication of Tumen and Piersol.⁵ Bollman, Power and Mann⁶ feel that galactose is theoretically the sugar of choice for the testing of carbohydrate metabolism in hepatic disease.

The technic of the galactose tolerance test as carried out in this study is essentially that given by Shay and Schloss. After an overnight fast, the patient is instructed to empty the bladder, the specimen being used as a control for glycosuria. The patient is then given 40 Gm. of galactose dissolved in 500 cc. of water to which a few drops of lemon juice have been added. Specimens of urine are collected at hourly intervals for five hours and placed in separate containers. During the period of the test the patient may drink water if he desires, but nothing else. Each specimen is tested for sugar by means of the Benedict qualitative reaction.

Chart 1.—Galactose test in 100 cases of jaundice.

Those specimens giving a positive test are mixed and the total amount of sugar is determined by the Benedict quantitative method. An excretion of more than 3 Gm. is considered as indicative of intrahepatic jaundice and is referred to as a positive galactose test, whereas an output of less than 3 Gm. is referred to as a negative galactose test. Care must be taken to exclude the presence of oliguria, as it may result in an unreliably low output of galactose.

The technic of Rosenthal and White⁷ was employed in the tests of bromsulphalein excretion, 2 mg. of the dye being given per kilogram of body weight. It was thought preferable to employ this amount rather than

the larger (5 mg.) dose because of the presence of jaundice. The results expressed in the tables indicate the percentage of dye retained in the blood stream half an hour after injection. Normally, none of the dye should be detectable in the blood after this period of time.

The results of the galactose test are given in chart 1.

CATARRHAL JAUNDICE

There were fifty patients with catarrhal jaundice (table 1). The diagnosis was based on jaundice that was generally painless, of short duration, frequently

Chart 2 (case 48)—Relation between serum bilirubin galactosuria and bromsulphalein retention (catarrhal jaundice).

preceded by an infection of the upper respiratory tract, accompanied or shortly preceded by epigastric discomfort, and one that ended in recovery with the exception of two patients who died and were examined post mortem. Following subsidence of the jaundice, all patients over 30 years of age, and many of the younger individuals, were subjected to a Graham test and showed normal gallbladder visualization. Bile microscopy was negative with respect to calcium bilirubinate and cholesterin crystals.

In forty-seven of the cases a positive galactose test (excretion of 3 Gm. or more) was obtained on first

TABLE 2—Duration of Jaundice and Average Galactose Output (Catarrhal Jaundice)

Number of Cases	Duration of Jaundice	Average Galactose Excretion, Gm.
12	2-7 days	4.47
16	9-14 days	6.21
11	15-21 days	4.33
10	23-64 days	5.16
1	Uncertain	4.60

examination. In two others (cases 37 and 45) a second test, done five and four days, respectively, after the first, was positive, making forty-nine positive among a total of fifty cases. This agrees closely with the experience of Shay, Schloss and Rodis, who reported positive tests in all of sixteen patients with catarrhal jaundice. Tumen and Piersol obtained positive tests in eighteen of twenty-three cases (78.3 per cent).

The importance of repeating the test, particularly when early in the course of jaundice a discrepancy appears between clinical and laboratory observations, is illustrated in cases 37 and 45. The third case with a negative test (case 16) was an extremely mild one, the serum bilirubin not exceeding 5.7 mg. per hundred cubic centimeters and the jaundice disappearing on the twelfth day. It is interesting to note that the negative tests were all obtained in younger patients (aged 13, 22

and 26 years respectively), in whom differential diagnosis is generally less difficult and less urgent than in older individuals. The average galactose output was somewhat higher (5.33 Gm.) in nineteen individuals over 35 years of age than in the thirty-one individuals below this age level (4.99 Gm.).

In all of thirty-one patients in whom there was a history of an antecedent infection of the upper respiratory tract the galactose test was positive, the average

Chart 3 (case 40)—Relation between serum bilirubin galactosuria and bromsulphalein retention (catarrhal jaundice).

output in this group being 5.28 Gm., in contrast to an average of 4.85 Gm. in the remaining patients.

The galactose output does not appear to be directly related to the duration of jaundice. This has been the experience of Tumen and Piersol and others (table 2).

There also appears to be no direct relationship between the level of serum bilirubin, galactose output

and bromsulphalein retention (charts 2, 3, 4 and 5). At certain stages the galactose test may be the sole one to show evidence of liver damage. Chart 2 shows an increase and subsequent decrease in jaundice with constant galactosuria and later a slight degree of jaundice with a normal galactose output. Chart 3 shows an increase in galactosuria with a simultaneous decrease in the degree of icterus. The galactose output was still high in the absence of bromsulphalein retention. Chart 4 illustrates persistence of excessive galactosuria after

Chart 4 (case 25).—Relation between serum bilirubin galactosuria and bromsulphalein retention (catarrhal jaundice).

complete subsidence of icterus. Chart 5 shows a tendency of galactosuria to parallel icterus.

In thirty-two of the patients the liver was felt to be definitely enlarged, extending from one to four or more fingerbreadths below the right costal margin. The average galactose output in this group was 4.7 Gm. In the remaining eighteen patients the liver was not demonstrably enlarged, being either not palpable at all or barely felt at the end of deep inspiration. The average galactose output in this group was 5.19 Gm. The three individuals with an initial low galactose output (cases 16, 37 and 45) showed respectively no hepatic enlargement, one fingerbreadth and two fingerbreadths enlargement.

TOXIC HEPATITIS

Of fifteen cases of toxic hepatitis, the galactose test was positive in fourteen (table 3). This is to be expected in view of the changes found in acute catarrhal jaundice, which is felt to be a form of acute hepatitis. Banks, Sprague and Snell⁸ report positive tests in fifteen of eighteen cases of acute and subacute intrahepatic jaundice, including two cases of catarrhal jaundice. Tumen and Piersol obtained a positive test in only seven of thirteen cases of toxic hepatitis.

OBSTRUCTIVE JAUNDICE

The obstructive jaundice group comprised twenty cases (table 4). In eleven the jaundice was due to common duct stone. In six of these the diagnosis was confirmed at operation, while the remaining five presented the clinical signs of Charcot's intermittent hepatic fever associated with leukocytosis. Three of

these five patients, 8, 9 and 11, had had gallstones (and the gallbladder) removed one, three and seven years prior to admission. In the other two, after disappearance of the icterus, the gallbladder failed to visualize on repeated roentgen examination. In one, no B bile was obtained on repeated attempts at biliary drainage, while B bile obtained from the second individual contained calcium bilirubinate and cholesterol crystals.⁹

In four cases gallbladder disease was found at operation, with obstruction probably due to cholangitis in three and pancreatitis in the remaining one, in which a cholecystogastrostomy was performed.

In the remaining five cases, obstruction was apparently due to pancreatic carcinoma in four and pancreatic cyst in the fifth. In two of these cases diagnosis was based on the clinical observation of progressive, painless, fatal jaundice of long standing with complete obstruction associated with enlargement of the liver and gallbladder and with negative roentgen changes except for evidence of distortion of the duodenum.

As can be seen from a study of table 4, the galactose output was relatively low in every instance, regardless of the duration of the jaundice or the cause of the obstruction. It is interesting to note the drop in the galactose output in case 18 almost two months after the first test with practically little change in the degree of jaundice.

Our results are similar to those of Shay, Schloss and Rodis, who encountered negative galactose tests in all of eighteen cases of obstructive jaundice. Tumen and Piersol encountered only one positive test in eighteen cases. Banks, Sprague and Snell obtained negative galactose tests in only sixteen of thirty cases of carcinoma of the head of the pancreas or ampulla of Vater and primary neoplasm of the common or hepatic ducts. These authors also obtained negative tests in only two thirds of thirty-seven cases of jaundice due to choledocholithiasis, stricture, and cholecystitis and hepatitis and

Chart 5 (case 27).—Relation between serum bilirubin galactosuria and bromsulphalein retention (catarrhal jaundice).

cholangitis. We are unable to reconcile our results with those of these authors unless their patients had more extensive parenchymal hepatic injury.

CIRRHOSIS OF THE LIVER

There were ten cases of cirrhosis, of which eight were portal in type and two biliary in character (table 5). In four the galactose output was positive, while in six it was negative. Wagner¹⁰ also obtained four

8. Banks, B. M.; Sprague, P. H., and Snell, A. M.: Clinical Evaluation of the Galactose Tolerance Test, *J. A. M. A.* 100:1987-1993 (June 24) 1933.

9. The diagnosis in this case was subsequently confirmed by operation.
10. Wagner, F.: Klinische Untersuchungen über die Bedeutung der verschiedenen Zuckerproben für die Beurteilung der Leberfunktion, *Ztschr. f. klin. Med.* 80: 174-199, 1914.

positive tests among ten cases, while Banks, Sprague and Snell obtained but two positives among thirteen patients. Wagner examined hourly specimens until two that were sugar free were obtained. Baucr has more recently adopted this method because of the delayed excretion of galactose if oliguria is present.

Opportunity was afforded to examine microscopically the livers of three patients in this series. Case 1, which gave a positive test, showed in addition to the cirrhosis severe parenchymal damage (table 7), in the form of rarefaction and granularity of the cytoplasm of most of the liver cells and subacute hepatitis associated with beginning bile stasis. Case 9

diffuse cirrhosis considerable regeneration of liver tissue, a finding that has been invoked to explain some instances of a negative galactose test in cirrhosis. However, case 6, which also gave a negative test, showed very little evidence of regeneration.

Banks, Sprague and Snell report two instances of increased galactose excretion falling to normal as the patients recovered from brief episodes of jaundice.

patient developed ascites. A second determination done six weeks after the first showed the galactose output to have dropped to 1.1 Gm. Death occurred on December 17, on the one hundred and second day of jaundice. It is of interest to note the change in galactose output with the development of subacute cirrhosis. While the excretion of galactose may have been somewhat impaired as a result of the patient's condition, it is felt that this did not account for the difference in the two determinations, as on the occasion of the first test a total of 195 cc. of urine was obtained during the five hour period and during the second test 145 cc.

It is interesting to note the extensive types of liver damage other than acute with low galactose outputs as exemplified by the remaining cases with one exception (case 12).

ILLUSTRATIVE CASES

CASE 1 (case 50, catarrhal jaundice).—An obese white woman, aged 47, was admitted to the Medical Service of the Cincinnati General Hospital, Dec. 11, 1933, complaining of icterus of fifteen days' duration. This was preceded by an

CARCINOMA OF THE LIVER

In four of five patients, the galactose test was negative (table 6). This may be explained by the fact that enough of the liver parenchyma was not destroyed (or injured) to interfere with conversion of galactose into glycogen. Banks, Sprague and Snell reported three positive tests in seven cases of malignant metastatic deposits in the liver. Wagner reports negative tests in extensive primary hepatic neoplasm. According to Bauer,¹¹ metastatic malignant lesions of the liver rarely produce any significant change in galactose tolerance.

ANATOMIC HEPATIC CHANGES

The liver sections of twelve of the patients were studied by Drs. R. S. Austin and Pearl Zeek of the department of pathology. The results are recorded in table 7.

In two cases giving positive galactose tests, severe parenchymal injury was found (cases 1 and 3). The third patient (patient 2) was admitted with catarrhal jaundice. On the forty-second day of icterus, the galactose output was found to be 5.5 Gm. The jaundice persisted, the liver began to decrease in size and the

attack of severe epigastric pain radiating to her right shoulder blade and accompanied by nausea and vomiting. There was a history of indigestion during the preceding eighteen months. There was no history of an antecedent infection of the upper respiratory tract, ingestion of cinchophen or injection of arsphenamine. Her temperature on admission was 100 F. and there was considerable tenderness over the region of the right upper quadrant. The liver edge extended two fingerbreadths below the right costal margin, its surface being smooth and tender. The white cells numbered 10,400, with 74 per cent neutrophils. There was no anemia. The serum bilirubin was 20 mg. per hundred cubic centimeters, van den Bergh reaction direct, and urobilinogenuria negative. The impression of both internists and surgeons who saw the patient was one of common duct stone. The galactose output was 4.5 Gm. On the basis of this finding, surgical intervention was less seriously considered and a diagnosis of catarrhal jaundice was made. A week after admission, the jaundice began to decrease rapidly and recovery was uneventful. A Graham test later showed a normally visualized gallbladder, and repeated bile microscopy failed to reveal calcium bilirubinate or cholesterol crystals.

CASE 2 (not included in the reported series).—A white man, aged 66, was first seen about four months after the onset of a painless jaundice that was accompanied by marked anorexia, weakness and loss of weight. Pruritus was prominent. Examination revealed the liver edge to extend three fingerbreadths below the level of the right costal margin in the nipple line; the surface was smooth and not tender. The spleen was not felt. There was no ascites. The serum bilirubin was 4.9 mg.

11. Bauer, R.: Unsere Kenntnisse über Leberfunktion und ihre Verwertung für die Klinik, Wien. klin. Wchnschr. 45: 1577 (Dec. 23) 1932.

per hundred cubic centimeters; the galactose output 5 Gm., and bromsulphalein retention 60 per cent. Urobilinogen was present in the urine in excess. Roentgen examination of the gastrointestinal tract was negative. On the basis of excess galactosuria (and urobilinogenuria) a diagnosis of an atypical and unusually prolonged catarrhal jaundice with possible subacute necrosis was made. The patient's condition has steadily improved on a high carbohydrate, low fat regimen, together

In view of the excessive galactosuria (and urobilinogenuria) a diagnosis of an unusually prolonged catarrhal jaundice was made. There was a rapid decline in the patient's icterus, and recovery was uneventful.

SUMMARY AND CONCLUSIONS

The galactose tolerance test was positive (output of galactose exceeded 3 Gm.) in forty-nine of fifty cases of catarrhal jaundice and fourteen of fifteen cases of acute toxic hepatitis.

A negative test (output of less than 3 Gm.) was obtained in all of twenty cases of obstructive jaundice.¹² Negative tests were mostly obtained in cases of cirrhosis and neoplasm of the liver.

with frequent transduodenal biliary drainages. After eight months there are no abnormal findings except for slight increase in the size and consistency of the liver (one fingerbreadth below the right costal margin).

CASE 3 (case 24, catarrhal jaundice).—A white man, aged 62, was admitted to the Cincinnati General Hospital complaining of a painless jaundice of four weeks' duration. Anorexia and weakness were prominent and there was considerable loss of weight. There was no pruritus. The temperature was normal and the abdominal examination gave negative results. Serum bilirubin was 21.6 mg. per hundred cubic centimeters, bromsulphalein retention 90 per cent, galactose output 4.5 Gm. There was no urobilinogen in the urine. The admission diagnosis was carcinoma of the head of the pancreas. A diagnosis of catarrhal jaundice was later made because of the marked galactosuria. The patient died suddenly, seven days after admission, and autopsy revealed changes associated with acute hepatitis.

TABLE 6.—*Carcinoma of the Liver*

CASE 4 (case 22, catarrhal jaundice).—A white woman, aged 54, was admitted to the Cincinnati General Hospital, complaining of a painless jaundice of five and one-half weeks' duration. There was marked pruritus. She had lost 25 pounds (11 Kg.). The temperature was 99.2 and the abdominal examination negative except for a firm, smooth, moderately tender liver, which extended two fingerbreadths below the right costal margin. Serum bilirubin was 21.5 mg. per hundred cubic centimeters, bromsulphalein retention 100 per cent, galactose output 4.2 Gm. Urobilinogenuria was present in excess. Roentgen examination of the gastro-intestinal tract was negative

12	Common duct stone	1.3†	0.0	0.7	Liver changes scant; slight focal fatty infiltration; slight focal degeneration in central zones; slight periportal lymphocytic infiltration

* Secondary to carcinoma of pancreas.

† 7.3 mg. per hundred cubic centimeters three days previously.

The test appears of great value in differentiating acute (toxic or infectious) jaundice from obstructive (extrahepatic) jaundice.

The galactose tolerance bears no direct relationship to the degree or duration of jaundice or to the amount of retention of bromsulphalein. In the later stages of acute intrahepatic damage it may remain positive when other tests of liver function have become negative.

The test should be repeated when a discrepancy arises between clinical and laboratory observations.

12 Since this report was completed a case of carcinoma of the head of the pancreas with jaundice of eight weeks' duration (serum bilirubin 25 mg. per hundred cubic centimeters) was seen with a galactose output of 3.1 Gm.

ABSTRACT OF DISCUSSION

DR. HARRY SHAY, Philadelphia: The authors have presented data that should convince the most confirmed skeptic of the value of the galactose tolerance test in the clinical differentiation between toxic or infectious jaundice encountered in acute diffuse liver cell damage, and jaundice due to obstruction. The data portray clearly the usual results obtained with this test. It is difficult to reconcile their almost consistent results, the results reported this morning by Dr. Rosenberg of Chicago before the Section on Gastro-Enterology and Proctology, and my own previously recorded data, with those recently published by Banks, Sprague and Snell, in which the test did not show so favorably. The difficulty, I believe, lies not in the test itself but in the varying behavior of galactose metabolism in different types of liver cell damage. In studies on metabolism of galactose, as well as in the application of this test in jaundice, I have stressed certain very obvious facts concerning the function of the liver. First, the carbohydrate function of the liver is a vital one as has been adequately demonstrated by Dr. Mann and his associates. Second is the tremendous reserve of the liver and, third, the great power of regeneration. Because of the physiologic facts mentioned, no impairment of galactose utilization is seen unless the liver is involved acutely and diffusely. Then are seen high excretions of galactose in so-called catarrhal jaundice, in reality a diffuse hepatitis, and in cases of toxic or infectious jaundice from other damaging agents. In cases of obstructive jaundice, however, also a positive galactose tolerance test is seen when the obstruction has lasted for so long a period that the accumulated damage has overcome the reserve of the liver, by prolonged obstruction alone or obstruction plus infection, or when the regenerative power of the liver has failed. The discrepancy between my results and those of the present authors and of Dr. Rosenberg, as contrasted with the data of Banks, Sprague and Snell, may be due entirely to this fact. I am reasonably certain that the cases studied by the latter workers at Rochester, Minn., were of long duration or presented associated infection of the biliary tree, facts that would explain why they obtained such a high percentage of positive results in their obstructive jaundice group. It is true that this test is not a measuring stick in the experimental sense; but when one is confronted with the task of attempting an early differential diagnosis in jaundice, particularly in the painless jaundice of middle and later life, the test becomes of inestimable value. It is a simple office procedure. If done early and repeated, and if the physiologic principles for the interpretation of results are properly considered, the apparent failures of the test will be very few.

DR. F. C. MANN, Rochester, Minn.: The so-called liver function tests were first developed on the basis that hepatic function can be measured. The evidence today would indicate that liver function cannot be quantitated by any one test or any combination of tests. It would also appear that there is a dissociation of functions of the liver; that is, one function may be injured by a pathologic process without greatly interfering or even affecting other functions of the organ. It is logical, then, to do what the authors have done, to employ two or more tests in attempting not to quantitate hepatic function but to find out whether one function is more affected than another. While the tests cannot be used really to measure hepatic function, such data as the authors have presented may be accumulated, which may indicate that the tests can be used to differentiate various pathologic processes in the organ. The work in my laboratory would indicate that the liver is responsible for the utilization of a high percentage of galactose; that is, a dehepatized animal appears to utilize only a small amount of the galactose administered to it. This is entirely different from the administration of levulose to a dehepatized animal, in which case the animal can utilize a high percentage of the levulose administered, or dextrose in which it appears to utilize all of it. Experimentally the test has not proved to be of much value in quantitating hepatic function because of the marked variability in the ability of the animal to utilize this sugar. I believe that the authors' employment of the various tests to differentiate the pathologic processes in the liver rather than to attempt to quantitate liver function is of value.

AND

HENRY W. WOLTMAN, M.D., ROCHESTER, MINN.

The etiology of neuronitis of pregnancy is still in question. Until recently, this condition was usually considered as being due to a toxemia associated with pregnancy. It is now generally believed, however, that it is caused by a deficiency in vitamins, such deficiency usually being attributed to the excessive vomiting that occurs among patients who develop the disease.

A review of the literature reveals the high incidence of vomiting in cases of neuronitis of pregnancy. Of the fifty-two cases, reports of which were collected by Berkwitz and Lufkin,¹ in only one was it specifically stated that vomiting had not been noted. Caffier,² Wilson and Garvey,³ McGoogan,⁴ Strauss and McDonald,⁵ Luikart,⁶ Lubin⁷ and Gillespie⁸ have all reported cases of this disease, and in each one of these severe vomiting occurred prior to the onset of neurologic symptoms. Vandel⁹ has reported three cases in which the patients had neuronitis; two of them had hyperemesis, and the third, a semistarved woman, was in a very poor nutritional state. Hornung and Creutzfeldt¹⁰ reported two cases in which paralysis was associated with pregnancy; in one of these they considered the paralysis to be the result of neuronitis associated with vomiting, and in the other, in which vomiting did not occur, they attributed the paralysis to concurrent infection, poliomyelitis. Although Plass and Mengert¹¹ do not give the protocols for their twelve cases, they state that "gestational polyneuritis almost invariably develops late in the course of or following an attack of hyperemesis gravidarum."

Strauss,¹² in his most recent article discussing the rôle of the gastro-intestinal tract in conditioning deficiency diseases, stated that "the disease [polyneuritis of pregnancy] occurs only after 'pernicious vomiting' of pregnancy. It is thus apparent that the failure of the gastro-intestinal tract to retain food can cause this deficiency." A case of neuronitis of pregnancy recently has come under our observation, which refutes the dogmatism implied by this statement and which casts doubt on the universal validity of the theory of vitamin deficiency. We are reporting this case not to describe the disease, which has been amply done in the literature, but to focus attention on the fact that neuronitis of pregnancy may occur without vomiting and without any gross dietary deficiency.

REPORT OF CASE

A married woman, aged 31, came to the Mayo Clinic, April 30, 1934, complaining of paralysis of the right leg and weakness of the left leg, both of four and a half months' duration. Her history is significant. As a child she had had scarlet fever.

In 1918 she had had influenza. She had then been well until six weeks before the birth of her first child, in 1929. At that time a peculiar feeling in both arms had developed. She found it difficult to describe this feeling, saying "It was not a real numbness nor a tingling but just a funny sensation." In addition her arms seemed to be weak, and for no reason she could explain she had suddenly dropped things. This condition had cleared up entirely immediately after the birth of the child. Vomiting had not occurred at any time during the pregnancy.

Six or eight weeks before the birth of the patient's second child, in 1931, the same symptoms developed in her arms, although in addition she now had numbness and tingling in her legs, which at times would suddenly buckle up under her. Again all her symptoms disappeared completely after the child was born. There was no vomiting during this second pregnancy.

Six weeks before the birth of a third child, 3 months old at the time of the patient's admission, the patient had a severe right renal colic, which was followed the next day by hematuria and by the passage of small calculi. Two days after this attack her right leg became weak, and within three or four days it was completely paralyzed. The left leg became weak at the same time, but it never was completely useless. The back and abdominal muscles became involved, the patient being unable to sit up in bed. There seemed to be no loss of strength in the arms. She complained, however, of moderately severe, fleeting pains in both the arms and legs and of a peculiar, numb feeling of the legs. This condition remained stationary until after delivery, when there was marked improvement in the use of the left leg but very little return in function of the right. The back and abdominal muscles became slightly stronger.

negative. Examination of the ocular fundi gave negative results. The perimetric fields were normal.

Laboratory Examination.—The urine was of a specific gravity of 1.028 and was acid in reaction; it contained a slight amount of albumin and a large amount of pus but no sugar. The value for hemoglobin was 12.4 Gm. per hundred cubic centimeters of blood, and erythrocytes numbered 4,030,000 and leukocytes 6,500 per cubic millimeter. The differential count was normal; morphologically, the blood picture was that of mild, hypochromic anemia. The flocculation test was negative. Roentgenologic study of the thorax gave negative results. Examination of the spinal fluid gave the following results: Wassermann reaction, negative; globulin, positive; small lymphocytes, 3 per cubic millimeter; total protein, 0.40 Gm. per liter; colloidal gold, 0001200000; pressure, 90 mm. on the water manometer; prompt response to jugular pressure up to 230 mm., prompt fall.

THE CASE AGAINST THE A. B. & S. PILL

FREDRICK F. YONKMAN, Ph.D., and HARKISHEN SINGH, D.M.D., BOSTON

The cathartic agent known as the A. B. & S. pill, even though relegated to the National Formulary, is still rather freely recommended by some practitioners and consequently is promiscuously used by the public. Hence there are frequent disastrous consequences when these pills are eaten by unsuspecting youngsters, who presume that the beautifully colored and sugar-coated pellets are "candy" rather than "deadly buck-shot" by virtue of the contained strychnine which accompanies the belladonna and aloin.

Fig. 1.—Man, aged 52; Cecostomy, March 2, 1934. Time interval in minutes. At 12:10 p. m., 3 mg. of strychnine intramuscularly.

Again during this third pregnancy there had been no vomiting, and prolonged inquiry did not reveal any gross dietary deficiency during this or the other pregnancies. The diet seemed to be adequate in amount and in vitamin content. There was no history of exposure to metals, and no medication was taken at any time during the pregnancies.

The functional inquiry gave essentially negative results. At no time was there diplopia, loss of vision, facial paralysis, speech defect or loss of sphincter control.

Physical Examination.—The patient was well developed and moderately obese. Her eyes reacted to light and in accommodation; the pupils were equal and regular. Small tonsillar tags and mild gingivitis were present. The thyroid gland was slightly enlarged and soft, but there was no bruit or thrill. Examination of the heart, lungs and abdomen gave negative results. Pelvic examination likewise gave negative results except for indicating a badly lacerated cervix. Rectal examination revealed small hemorrhoids.

Neurologic Examination.—The cranial nerves were normal. There was no nystagmus. The muscles of the head, neck and upper extremities were normal. The back and abdominal muscles were markedly diminished in strength. The muscles of the left thigh were moderately weak and the muscles of the left leg were slightly weak. There was no atrophy of this leg.

The muscles of the right thigh were almost completely paralyzed and the muscles of the right leg completely so. The muscles of this leg were moderately atrophied. There was no fibrillary twitching in either leg. The arm reflexes were brisk and the abdominal reflexes normal. The patellar reflex was absent on the right and was just obtained with reinforcement on the left. The achilles tendon reflex was absent on the right and normal on the left. There was bilateral flexor response of the Babinski reflex. The sensory examination was

The danger of all disguised medicants containing strychnine is vividly portrayed by Aikman¹ in his analysis of agents responsible for death preceded by convulsions in children under 5 years of age. He finds that strychnine in the form of Hinckle's, A. B. & S., and A. B. S. & C. pills or tablets is the most frequent causative poisoning agent.

In 1929 in Dr. O. H. Plant's laboratory at Iowa City, experiments² with various doses of strychnine were conducted by the "balloon method"³ on unanesthetized trained dogs with Thiry-Vella loops of the ileum. As a result of these studies, which showed slight but definite increased activity of the dogs' small intestine, the following statement was made: "If we are justified in transferring these results, obtained in dogs, to the human subject on a basis of per kilogram dosage, then the use of strychnine to increase muscular activity of the intestine or to make other drugs more effective, is warranted as a therapeutic measure."

May we frankly state, however, that we have long been of the conviction that drugs less hazardous than strychnine are available for purposes of either promoting or augmenting catharsis.

Not until Aikman's review appeared were we cognizant of the actual frequency of convulsive poisoning by strychnine. His paper convinced us of the desirability of ascertaining by the graphic, balloon method the effect of therapeutic doses of strychnine in man.

METHOD

Long, sausage-shaped balloons tied to rubber catheters were inserted through cecostomies and colostomies into the large intestine of four patients, one woman and three men.⁴ The catheter was then connected to a water manometer in which any change in water level and hence in air volume was distributed graphically to a smoked paper on the kymograph through a modified⁵ Brodie air bellows. All patients were given breakfast and the balloon was usually inserted, without pain in any instance, at about 9:30 or 10 a. m. The patient was allowed to assume a comfortable position on his back in

Fig. 2—Woman, aged 54. Cecostomy, June 19, 1933. Time interval in minutes. At 4 16 p. m., 2 mg. of strychnine intramuscularly.

his own bed and changed only slightly from this position for four, six or seven hours with little discomfort. All injections of strychnine sulphate were given intramuscularly, after a normal record of one hour's duration had been obtained.

RESULTS

In five experiments on four patients there was no recognizable change in either tone or peristalsis, in three instances following

Fig. 3—Man, aged 55. Colostomy, Feb. 15, 1934. Time interval in minutes. At 12.01 p. m., 3 mg of strychnine intramuscularly.

2 and 3 mg. of strychnine; only slight increase in peristalsis in one case after 3 mg., and considerable depression of peristalsis in another when 2 mg. was given. The accompanying tracings are representative.

COMMENT

Our results are taken from only five experiments in four cases but these we hope to supplement presently and to report when a sufficient number accrues. From the data at hand it seems that strychnine in doses found in the A. B. & S. pill

some significant increased activity seen in a previously lethargic colon. This slight increase, however, was obtained with three times the therapeutic dosage when employed in the form of the A. B. & S. pill.

If little or no effect is obtained in most cases of strychnine intramuscularly, one might reasonably expect less effect, if any, after oral administration with its subsequent less accurate dosage, dependent obviously on varying degrees of intestinal absorption.

From this work we cannot say that strychnine in 2 and 3 mg. dosage does not augment catharsis promoted by aloin orally, but we can conclude that in itself it has little if any effect when administered intramuscularly. To lend weight to our suspicion that it does not synergize or augment aloin activity we quote from Fantus,⁶ who says: "Nothing may seem more logical than to add to the aloin some strychnine for the purpose of increasing the irritability of the motor neurons on which the aloin is to act; nor might it seem that anything would be more suitable to counteract the reputed tendency of aloes to produce griping than the powerful antispasmodic belladonna. Unfortunately, by utilizing them in pill form at the same time they cannot possibly act together because of the different speed and duration of action of the three agents. Aloin is slow in action, requiring from ten to twelve hours—that is why it is generally given at bedtime. Strychnine and atropine, on the other hand, are rapidly absorbed and rapidly excreted, having but a brief duration of action. No experienced clinician would expect either of these alkaloids to act for more than four hours. By the time the aloin gets its

action in, the alkaloids have long since left the system by excretion into the urine."

If the results reported here are indicative of what may be expected from a larger group of cases, we feel strongly with Dr. Aikman that something should be done to "save the youngsters" against accidental strychnine poisoning. This was again vividly brought to mind recently when four small children were brought into the Boston City Hospital in convulsions as a result of having eaten "candy," according to the two

Fig. 4.—Man, aged 48: Colostomy, Feb. 13, 1934. Time interval in minutes. At 11:08 a. m., 2 mg. of strychnine intramuscularly.

(0.5 mg. per pill) is of no value. This seems particularly evident from the three cases reported here, in which strychnine in two and three times the amount found in a therapeutic dose of two pills (1 mg.) was injected without results. Further, twice the therapeutic amount actually caused depression in one case of a moderately active colon. In only one instance was

survivors of the group. This case illustrates the point—the children were playing in a vacant lot when one youngster happened on a bottle containing nicely colored "candy" (A. B. & S. pills). This bottle had been thrown from an adjacent apartment window when the tenants cleaned the medicine chest prior to vacating.

Adults, usually unaware of the dangerous constituents of the cathartic tablets, carelessly leave the bottles and contents

4. We are greatly indebted to Dr. W. R. Morrison, Dr. E. S. A. King and Miss Agnes MacDonald, R.N., of the Boston City Hospital for their hearty cooperation in this investigation.

6. Fantus, Bernard: Useful Cathartics, Chicago, American Medical Association, 1927, p. 133.

within reach of unsuspecting youngsters. These children can be protected only by having proper emphasis laid on the potential death-dealing components—particularly strychnine. This can best be done by (a) leaving the pill uncoated so that the bitter alkaloids will be repulsive to the child, (b) controlling more rigidly the sale of strychnine pills and tablets or (c) through adequate pharmacy laws prohibiting the inclusion of strychnine in any coated pill form, since its use seems unwarranted. The latter seems most desirable.

SUMMARY

1. Strychnine, in amounts two and three times that found in the usual compound pills, has little or no effect in promoting activity of the colon, as observed by the "balloon" method in man with cecostomy and colostomy.

2. Since strychnine poisoning is most common in small children and usually results from mistaking sugar and chocolate-coated cathartic tablets and pills such as Hinckle's Cascara and A. B. & S. for candy, the inclusion of strychnine in this type of medication should be prohibited.

TYROSINOSIS: A SEARCH FOR ADDITIONAL CASES

N. R. BLATHERWICK, Ph.D., NEW YORK

Medes¹ has described a condition in which a male patient was unable to metabolize tyrosine in a normal manner and has given the name of tyrosinosis to this error of metabolism. The patient was not capable of metabolizing tyrosine beyond the stage of *p*-hydroxyphenylpyruvic acid but retained the ability to oxidize homogentisic acid. The inability to metabolize the latter substance characterizes the condition of alcaptonuria.

When I heard of this new error of metabolism, I agreed to make a search for additional cases. The urine of Medes' patient had reducing properties and also gave a positive Millon's reaction. I therefore subjected all urine specimens that showed a slight amount of reduction by Benedict's picrate method for sugar to an additional test for the reduction of phosphomolybdic acid. This was used as suggested by Medes, as follows: To 1 cc. of urine in a test tube is added 2 cc. of Fiske and Subbarow² reagent (2.5 per cent ammonium molybdate in sixth normal sulphuric acid). Then 20 cc. of distilled water is added and the mixture is allowed to stand at room temperature for ten minutes. Normal urine at this time gives only a very faint greenish tint. In tyrosinosis a deep greenish blue develops. In case there was some reduction of the phosphomolybdic acid, I made the Millon test according to the procedure of Folin and Ciocalteu.³

Before these tests were applied to the specimens they were tried with a sample of the patient's urine and found to respond as described. During the period from April 25, 1930, to June 5, 1934, the molybdic acid test was applied to 16,838 specimens containing from 0.25 per cent to 0.5 per cent of sugar as determined by the Benedict picrate method. Also 9,354 specimens having more than 0.5 per cent sugar were tested. A few specimens gave a more or less blue or green color but failed to respond to the Millon test. One specimen was positive with both tests. However, a subsequent specimen from the same man and specimens from his two sons obtained after eating a meal rich in protein failed to give either test. It was decided that this man might have taken something which caused the positive observations with the first specimen. Dr. H. C. Fidler of Easton, Pa., kindly cooperated in obtaining these specimens. The results reveal the extreme rarity of this error of metabolism, not one case having been found in more than 26,000 examinations. Tyrosinosis certainly occurs less often than does alcaptonuria.⁴

GRANULOPENIA FOLLOWING ALLONAL

CHARLES H. STONE, M.D., AND JULIUS MARGOLIS, M.D.
COATESVILLE, PA.

E. J., a woman, aged 60, of Norwegian parentage, was admitted to the Coatesville Hospital, July 8, 1934, complaining of weakness and lassitude of two months' duration.

The family history showed nothing of importance. Her past history revealed that she had a repair of a cystocele in 1929. She was treated for carcinoma of the cervix uteri in July 1931 with radium. This was repeated in 1932 and 1933. In August 1933 and April 1934 she was given high voltage roentgen therapy for the same condition.

On account of insomnia, a physician advised her to take allonal (allylisopropylbarbituric acid with amidopyrine) tablets. From February 1934 until July 22, 1934, she took two of these tablets every evening before bedtime.

The present illness had a gradual onset in the early part of May 1934 with "loss of strength." About June 15 her gums and throat became very sore, associated with swelling of the glands of the neck. About the same time three abscesses developed in the gluteal region. The angina had almost entirely cleared up on admission to the hospital on July 8.

The patient was pale, poorly nourished and well developed. She was too weak to sit up and became exhausted on the slightest exertion. The heart sounds were normal. The pulse was rapid and weak, about 110 per minute. The temperature was 102 F. There was an advanced carcinoma of the cervix uteri with no evidence of metastasis.

Laboratory examination, July 9, revealed: red blood cells, 2,160,000; hemoglobin, 55 per cent (Tallqvist); white blood cells, 5,700; polymorphonuclear leukocytes, 12 per cent; lymphocytes, 58 per cent; large mononuclears, 18 per cent; transitionals, 4 per cent; basophils, 8 per cent. The red cells showed moderate anisocytosis and poikilocytosis. Examination of the urine showed a light cloud of albumin, occasional pus cells and occasional red blood cells. The Wassermann reaction was negative. Smear and culture of a gluteal abscess showed a few pus cells with a growth of *Staphylococcus aureus*. Blood culture, July 9, yielded no growth.

The patient was given blood transfusions of whole blood by the direct method: July 11, 120 cc.; July 13, 175 cc.; July 15, 175 cc.; July 19, 120 cc.; July 23, 200 cc. As a result of the transfusions the hemoglobin was raised to 75 per cent and red blood cells to 4,180,000, July 20. In spite of this increase in red blood cells and hemoglobin the white cell count on July 20 was only 2,800, with 2 per cent polymorphonuclear leukocytes. July 30 there were only 1,200 white blood cells, and no polymorphonuclear leukocytes could be found in a smear.

The temperature was of a septic type, ranging from 98 to 103. The fever continued until July 30, eight days after the allonal tablets were stopped. Since July 30 the temperature has been normal.

July 22 the allonal tablets were discontinued. Beginning July 25, pentnucleotide and liver extract were injected every day and later every other day until the time of patient's discharge from the hospital, August 11.

A white count and differential, August 6, showed that the white cells had gone to 4,900 and that of these 55 per cent were polymorphonuclear leukocytes. September 10 the white cell count was 6,100, with 69 per cent polymorphonuclear leukocytes.

Clinically, the patient began to improve a few days after the allonal tablets were discontinued. The abscesses of the buttocks and soreness of the gums had cleared up at the time of discharge from the hospital. The patient now feels much stronger and is able to be about.

This case is interesting because of the fact that the bone marrow function had been apparently depressed by the high voltage therapy and probably by toxins elaborated from the carcinoma previous to the administration of the allonal tablets. Kracke and Parker¹ have pointed out that, "in the clinical or experimental development of granulopenia, it is necessary to presuppose the existence of a previously weakened, damaged or idiosyncratic bone marrow which may be congenital or acquired."

Special Article

ALTHOUGH A NUMBER OF BACTERIOPHAGE AND ANTIVIRUS PRODUCTS HAVE APPEARED ON THE MARKET DURING THE PAST SIX YEARS, RELATIVELY FEW HAVE BEEN SUBMITTED TO THE COUNCIL ON PHARMACY AND CHEMISTRY. NONE HAVE BEEN ACCEPTED FOR INCLUSION IN NEW AND NONOFFICIAL REMEDIES. INQUIRIES FROM PHYSICIANS, HOWEVER, AND THE ADVERTISEMENTS OF MANUFACTURERS INDICATE THAT THE EXPLOITATION OF THESE PREPARATIONS IS SUFFICIENT TO WARRANT THE PUBLICATION OF A REPORT ON THEM. AS THE SUBJECT IS RELATIVELY NEW AND OBSCURE, AND AS THE PUBLISHED ACCOUNTS OF BACTERIOPHAGE THERAPY ARE CONFLICTING, IT IS OBVIOUS THAT A REPORT LIMITED TO COMMENTS ON THE COMMERCIAL PREPARATIONS WOULD HAVE ONLY A RESTRICTED USEFULNESS. BELIEVING THAT PHYSICIANS DESIRE A MORE EXTENSIVE PRESENTATION OF INFORMATION ABOUT BACTERIOPHAGE AND THE PRINCIPLES AND POSSIBILITIES OF BACTERIOPHAGE THERAPY, THE COUNCIL ON PHARMACY AND CHEMISTRY HAS AUTHORIZED THE PUBLICATION OF THIS REVIEW. IN ADOPTING THIS REPORT THE COUNCIL EXPRESSED APPRECIATION OF THE EXCELLENT WORK OF DRS. EATON AND BAYNE-JONES. PREVIOUS INSTALLMENTS OF THIS REVIEW APPEARED IN THE JOURNAL DECEMBER 8 AND 15. IT IS CONCLUDED IN THIS ISSUE.

PAUL NICHOLAS LEECH, Secretary.

BACTERIOPHAGE THERAPY

REVIEW OF THE PRINCIPLES AND RESULTS OF
THE USE OF BACTERIOPHAGE IN THE
TREATMENT OF INFECTIONS

MONROE D. EATON, M.D.
AND
STANHOPE BAYNE-JONES, M.D.
NEW HAVEN, CONN.

(Concluded from page 1853)

Bacteriophage in the Treatment of Plague.—d'Herelle,¹²³ reported successful results from the injection of a highly "virulent" bacteriophage into the buboes in four cases of bubonic plague. He stated that, as a result of bacteriologic examination of the buboes, lysis of the organisms in vivo had occurred. Pons¹²⁴ and Couvy,¹²⁵ as a result of more detailed studies, have also come to the conclusion that lysis of the organisms in vivo occurs in cases of plague injected with bacteriophage. Couvy¹²⁶ treated twenty-one cases of plague with bacteriophage and observed a mortality of 33 per cent. In 124 serum treated cases the mortality was 65.3 per cent. In a following year this author further studied 245 cases of plague. Seventy-two of these patients died within less than twenty-four hours after admission to the hospital and were not treated with bacteriophage. In the remaining 173 cases treated with bacteriophage the mortality was 31 per cent, but the total mortality, including the patients who died less than twenty-four hours after admission, was still around 60 per cent. Although this series of cases is probably large enough to be significant, the controls and statistical treatment of the results are open to question. Robic¹²⁷ treated four cases of pneumonic and five cases of bubonic plague with a bacteriophage which was active for the organisms isolated from the cases. Contrary to the observations of Pons, he found the organs infested with *B. pestis* after death. The bacteriophage therapy appeared to have little effect in these cases. Naidu and Avari,⁴⁰ using a highly active bacteriophage in studying the effects of bacteriophage and serum in 200 cases of plague, found the bacteriophage to have

very little therapeutic value. In the 200 treated cases the bacteriophage was injected into the buboes, intravenously, and also given by mouth. Ninety-seven control cases received serum treatment alone. In cases receiving both bacteriophage and serum the mortality was higher than in the group receiving only serum.

The evidence, based on a considerable number of cases, for the therapeutic value of bacteriophage in plague is contradictory and for the most part points to the negative side. It seems certain that d'Herelle's early reports of dramatic cures of this disease have not been confirmed by later studies.

For other references and reviews on bacteriophage therapy the reader is referred to the following papers: Hauduroy,¹²⁸ Hadley,¹²⁹ Bronfenbrenner,⁶ Schultz,¹²⁹ d'Herelle,¹³⁰ Larkum,¹³¹ Charnock¹¹⁰ and Hoder.³²

4. *Discussion of the Mode of Action of Bacteriophage Lytic Filtrates in Vivo.*—So far the most convincing evidence presented for the therapeutic value of the bacteriophage lytic filtrates is in the various suppurative conditions and pyodermias, principally those caused by staphylococci. In certain cases of pyelitis and cystitis administration of bacteriophage also seems to have been of value. In other diseases the evidence is at present just as conflicting as it always has been since the first attempts at bacteriophage therapy over twelve years ago.

If we grant that the administration of the lytic filtrates may have some therapeutic value in certain diseases, it is necessary to look for some mechanisms other than lysis of bacteria in vivo to account for the favorable results obtained. It seems likely, on the basis of present evidence, that any appreciable lysis of bacteria in vivo seldom, if ever, occurs, except possibly in the bladder and walled off spaces where little exudate is present and where irrigation with large amounts of bacteriophage can be used. Oral administration of bacteriophage, as used in typhoid, dysentery and cholera, seems to have had little effect, and there is at present no convincing evidence that lysis of bacteria by bacteriophage occurs in the intestine, even though the lytic agent may reach the intestinal canal by the oral route. Even d'Herelle^{130b} emphasizes the fact that "the phenomenon of bacteriophagy in vivo is far more complex than that occurring in vitro."

In spite of the large amount of published work on bacteriophage therapy it is not at present certain whether the bacteriophage itself or other constituents of the lytic filtrates produce the effects observed. Bazy⁸² found that heated filtrates, or filtrates of autolyzed cultures free of active bacteriophage, produced improvement in staphylococcal infections comparable with that resulting from the administration of bacteriophage. Gratia and Doyle,¹³² in studies on experimental cholera and *B. coli* infections in guinea-pigs, found that filtrates of old autolyzed cultures containing no bacteriophage injected from twenty-four to forty-eight hours before infection conferred the same degree of protection as bacteriophage filtrates. They also observed that *B. coli* filtrates

with or without bacteriophage produced some degree of protection against cholera. Brouardel¹³³ has also observed nonspecific therapeutic effects from the use of bacteriophage filtrates.

One effect of the bacteriophage itself that has received too little consideration in the discussion of the mechanism of action *in vivo* is the ability of the lytic agent to produce avirulent forms of bacteria from virulent organisms, as shown by Hadley.¹³ This author believes that the therapeutic effects of bacteriophage are due to the production of bacterial dissociants which are easily destroyed by the usual bodily defense mechanisms. He cites a large amount of more or less indirect evidence to support this view, and it seems at present that this explanation may be even more likely than the assumption of *in vivo* lysis. A point against this view, however, is the known fact that dissociants are sometimes produced by the bacteriophage which are more virulent than the parent organism.

Among the effects of lytic filtrates which may or may not be due to bacteriophage are the production of increased leukocytosis and phagocytosis. Arnold and Weiss,¹³⁴ using Wright's technic, observed an increased phagocytosis *in vitro* which was proportional to the bacteriophage content of the preparations tested. Smith¹³⁵ and Nelson¹³⁶ confirmed these results and found that the phagocytosis of resistant organisms was not increased by the action of the bacteriophage preparations. The latter point indicates that the opsonizing action is due to the bacteriophage itself. Similar results have been obtained *in vivo* by MacNeal, Frisbee and Slavkin,¹³⁷ who observed increased phagocytosis of bacteria by the reticulo-endothelial cells of the spleen and liver during experimental staphylococcal septicemia in rabbits, treated by intravenous bacteriophage from two to twenty hours after infection, as compared with untreated controls. Nelson¹³⁶ observed that the intravenous injection into rabbits of staphylococcus bacteriophage together with susceptible organisms caused a much more rapid increase of leukocytes than did the intravenous injection of susceptible organisms alone. Repeated injections of bacteriophage caused a relative leukopenia. Injections of resistant organisms and bacteriophage produced only a slight effect on leukocytosis.

d'Herelle^{130b} has adhered to the view that bacteriophage causes increased phagocytosis in the body. He also supports the view of Hadley that microbic dissociation produced by the bacteriophage plays a part in therapeutic effects, but he also maintains that lysis occurs *in vivo*.

Among the effects that cannot be attributed specifically to the bacteriophage are the marked febrile reactions observed by a number of investigators after injection of the lytic filtrates. These reactions are probably nonspecific in nature and due to the bacterial proteins and substances from the nutrient broth contained in the preparations. Petersen¹³⁸ has adequately reviewed the large amount of work on the nonspecific effect of the injection of foreign proteins and bacterial

vaccines into the body. There are cited many instances of great benefit or prompt recovery, in various infectious diseases, resulting from the injection of foreign proteins or vaccines. In this effect actual specific immunization plays no part.

A large number of investigators, as cited by Petersen, have observed many striking changes in the animal body as the result of injecting foreign proteins. There is a primary leukopenia followed by a later leukocytosis with a relative granulocytosis. Changes in the amount and proportions of blood proteins, the amount of fibrogen and the clotting time have been noted. There is an increase in complement which seems to have a close relation to the therapeutic effect. Studies of the chemistry of the blood give evidence of a primary acidosis, which is followed by a rather long continued alkalosis with corresponding changes in the reaction of the urine. Other changes in blood chemistry and the chemistry of various organs are noted. There is an increased nervous irritability, and changes in the autonomic system rendering it more susceptible to certain drugs, together with a distinct stimulation of the sympathetic nervous system.

The most important effects of nonspecific protein injections in relation to therapy of infections are the changes produced in the immunity mechanisms. It has long been a well known fact that injection of a nonspecific protein into an immunized animal promptly increases the specific antibody titer against the organism or protein used in immunization. In normal animals there is a transient increased protection against infection. This was first noted by Pfeiffer, who studied the effects of nonspecific injections on the resistance of guinea-pigs to cholera. Protein injection produces an increased permeability of the blood vessels throughout the body, followed by a reversal to impermeability. The reticulo-endothelium becomes temporarily more active and later shows greatly lessened activity. Increased body temperature is a well known result of injections of foreign protein.

Protein therapy seems to have been most successful in various chronic diseases with foci of infection. Typhoid is one of the few acute diseases in which protein therapy has yielded interesting results. Petersen reports that in approximately one third of the cases after protein therapy the patients recover by crisis, and in another third there is improvement in general symptoms. Petersen explains these results on the basis of increased blood flow and permeability in the splanchnic area, which results in partial or total destruction of the bacteria. Typhoid appears to be particularly favorable for nonspecific protein therapy because of the location of the lesions in the intestinal wall, where the effects of this method are most pronounced. In other local infections or in septicemias protein injections usually have little effect and are sometimes harmful. But even in these cases clinical experience has shown that prompt and spectacular recovery may take place after some nonspecific injection. As Petersen points out, increased antibody titer, reticulo-endothelial activity, enzyme mobilization with accelerated digestion of bacteria, changes in acid-base equilibria, leukocytosis and local accumulation of leukocytes all may play a part in these cases of dramatic recovery.

It cannot be emphasized too strongly that all these nonspecific effects of the constituents of bacteriophage preparations must be taken into consideration in any thorough investigation of the therapeutic effect of the agent. It would seem likely that these effects come

into play only when the agent is injected. However, protein reactions have been reported to occur following the ingestion of peptones, and it is not improbable that in the application of broth-soaked bacteriophage dressings to an open wound or hyperemic area there is opportunity for absorption of the bacterial proteins and peptones and other constituents of the medium. As already pointed out, few investigators have taken the trouble to control their clinical trials of bacteriophage by the use of preparations heated so as to destroy the lytic agent. Until this is done the reports of successful therapeutic use of bacteriophage will always remain unconvincing.

Another alternative explanation of the prompt results of bacteriophage therapy, especially when local applications or wet dressings have been used, is the antiviral effect of Besredka. This will be discussed in a separate section.

5. *Immunization with Bacteriophage Preparations.*—It was shown by d'Herelle in his studies on hemorrhagic septicaemia of water buffaloes that bacteriophage filtrates are capable of producing immunity. This observation has been confirmed and extended by a number of investigators working with various diseases in both animals and human beings. These effects are probably due to the development of antibodies to the bacterial proteins in the lytic filtrates and are in no way directly connected with the presence of the bacteriophage except so far as the action of this agent on the bacteria makes their proteins more available as antigens. Immunizing effects in bacteriophage therapy can be expected after injection of the preparations and the lapse of a certain amount of time, probably at least four days, before antibodies appear. Effects occurring after oral administration or local application and before the end of seventy-two hours cannot be ascribed entirely to development of immunity in the ordinary sense.

Larkum¹³⁹ has taken the view that the effects of bacteriophage preparations are due not to *in vivo* lysis, except in particular cases, but to the immunizing effects of the preparations. Thus these preparations play at least as important a rôle in prophylaxis as they do in therapy. In a study of the effects of typhoid vaccination in 200 human subjects, ordinary heat killed vaccine being used in about half the number and filtrates of bacteriophage lysed cultures in the other half, Larkum¹⁴⁰ made certain observations which indicate that the lysates are better antigens. The serums of the persons receiving one dose of lysate showed agglutinin titers equal to those receiving one dose of vaccine, but the bactericidal power of the blood and the opsonic index were higher in those receiving bacteriophage. The antibodies, after six months, in those receiving one dose of bacteriophage were higher than in persons receiving one dose of typhoid vaccine and equal to those having had three doses of typhoid vaccine. No reactions of any importance occurred in the bacteriophage treated group. More recently Larkum¹⁴¹ has claimed to have demonstrated that injection of bacteriophage gives rise to antitoxins. He showed that intravenous injections of bacteriophage in either twenty-five doses of 2 cc. each or one dose of 50 cc. produce in rabbits, after a brief period, a protection against massive intravenous

injections of living staphylococcus. The serums of protected animals are said to neutralize the dermonecrotizing staphylococcus toxin. Purified bacteriophage preparations are also said to produce antitoxins. To what extent Larkum is dealing with true exotoxins in this work, as distinguished from endotoxins or bacterial proteins, is not at present clear.

Arnold and Weiss¹⁴² have also placed emphasis on the immunizing effects of bacteriophage preparations used in therapy. They published a series of experiments in 1924 which indicate that the opsonic, precipitating and complement fixing antibodies of immune serums produced by bacteriophage are antibodies to the bacterial proteins and not to the bacteriophage itself. These authors later compared the immunizing effects of living, heat killed, and bacteriophage vaccines in experimental animals. They found that bacteriophage preparations produced the most rapid rise in phagocytic index and agglutinin titer, but after a longer period the living cultures produced a higher antibody concentration. Experiments on protection showed that the bacteriophage preparations produced a degree of protection out of all proportion to the antibody titer of the serums.

Other experiments on the immunizing effects of lytic filtrates have tended to confirm this evidence that such preparations are powerful antigens. Maslakowetz and Kasarnowsky¹⁴³ prepared an antigen from toxic Shiga dysentery bacilli by bacteriophage lysis which was weakly toxic for rabbits and atoxic for guinea-pigs. The antigen protected rabbits against at least ten minimal lethal doses of living cultures or toxin. Immunization of horses with the antigen yielded a potent antiserum in about two months. Nobechi¹⁴⁴ immunized guinea-pigs against from three to ten minimal lethal doses of cholera organisms by intraperitoneal injections of lysed cultures. Oral, subcutaneous or intravenous injections failed to protect. Arloing, Josserand and Nabonne¹⁴⁵ immunized rabbits by injecting intravenously a vaccine made by lysing heavy suspensions of typhoid bacilli with bacteriophage and, later, heating at 62 C. to destroy the bacteriophage. This vaccine produced serums with high agglutination titers, whereas vaccines made in the same way from unlysed heated typhoid cultures produced no agglutinins in rabbits.

A number of experiments on immunization against plague have been done in experimental animals with bacteriophage preparations. Compton,¹⁴⁶ in prophylactic experiments on mice with plague bacteriophage, showed that absolute immunity was produced in 40 per cent of the animals by two subcutaneous injections six days apart. Prophylactic use of stock vaccine under similar conditions produced an increased susceptibility rather than an immunity. In some of the animals receiving bacteriophage vaccine a hypersusceptibility was also observed. Compton believed that the immunity observed was probably antibacterial, not protobiotic, since no bacteriophage could be detected in the excreta and blood of protected animals. Flu¹⁴⁷ observed that white mice could be immunized by subcutaneous injections of large amounts of bacteriophage, but attempts at oral admin-

istration were unsuccessful. Later he¹⁴⁶ succeeded in immunizing 91 per cent of a group of rats against 400 lethal doses of plague bacilli by two or three subcutaneous injections of concentrated suspensions of bacteria lysed by bacteriophage. The protection appeared to be much better than that obtained with other vaccines.

Unfortunately the immunizing effects of bacteriophage preparations in human beings have been little studied, but the results of the experiments with laboratory animals indicate that the bacterial proteins contained in these preparations are very good antigens and in many cases produce a prompt response. This property of lytic filtrates indicates that such preparations may be of value in prophylaxis of disease, and possibly also in chronic or recurrent conditions. In the treatment of acute diseases with bacteriophage, little benefit may be expected from the immunizing effects.

6. Local Immunization and Antivirus Therapy According to Besredka.—This section is included in order to distinguish between the effects of the bacteriophage as such and the effects of a hypothetical substance in filtrates of bacterial culture not containing bacteriophage. Whether or not bacteriophage filtrates contain the so-called antivirus of Besredka has never been adequately demonstrated. Nevertheless, certain commercial bacteriophage preparations, especially those in which the lytic principle has been added to repeatedly inoculated broth cultures, are referred to also as antivirus, and for this reason a review of the theories of Besredka is necessary.

Besredka¹⁸ published his views on the phenomenon which he called local immunization as contrasted with the ordinary or general state of immunity, which follows the injection of antigens into an animal. He and a number of other investigators cited by him found that experimental animals could be protected against fatal infections with anthrax, streptococcus or staphylococcus by injecting intradermally or even by simply applying to the shaved skin vaccines or culture filtrates of the organisms. Besredka believed that the protective effect was due to local immunity in the skin, for which these organisms have an affinity. Animals so immunized showed no demonstrable circulating antibodies.

Guinea-pigs were protected against anthrax by rubbing on the shaved skin the first vaccine of Pasteur, followed after a period of several days by the second vaccine, then later by the virulent organisms. Immunization of animals against anthrax by the ordinary methods is said to be difficult, but Besredka claims that his method of cutaneous vaccination has proved successful both in laboratory animals and in the immunization against anthrax of cattle and horses when other methods failed. Experiments are cited which support the view that when injected into the peritoneum, trachea, brain or subcutaneous tissues, anthrax vaccines fail to immunize and virulent cultures fail to infect, provided the experiment is conducted in such a way that none of the organisms are brought into contact with the skin. These experiments have been both confirmed and contradicted by other investigators.

In extending his views to local immunization of the skin and mucous membranes in staphylococcal and streptococcal infections, Besredka cites a number of experiments in which filtrates of bacterial cultures are used as vaccines. The cutaneous vaccines for streptococcus and staphylococcus are prepared by filtering

8 to 10 day old broth cultures of the organisms. Such filtrates do not contain bacteriophage but undoubtedly do contain bacterial proteins resulting from the autolysis of the organism, as well as the metabolic products and substances contained in the nutrient broth.

According to Besredka, these broth filtrates are specifically inhibitory to the growth of the organism from which they were prepared, having no effect on the growth of unrelated species. The inhibitory substance is heat stable. Intraperitoneal inoculation of these broth filtrates has no immunizing effect, but when applied to the skin or mucous membranes in the form of wet dressings or injected intradermally they produce an immunity against local skin infections with staphylococcus or streptococcus. This immunity appears very rapidly, usually after about twenty-four hours, and therefore differs in this respect from ordinary immunity.

The hypothetical substance in these filtrates which specifically inhibits the growth of bacteria and produces rapid local immunization is called by Besredka "antivirus." Besredka claims to have immunized limited areas of the skin of animals by local application or intradermal injection of these filtrates, and the entire skin by more extensive application in the same way. He believes that local immunization of the skin or mucous membranes in staphylococcal or streptococcal infections is sufficient to protect against extension of the infection and that the inhibitory substance exerts a therapeutic effect by virtue of its specific inhibitory action on the infecting bacteria. According to Besredka's theory, the skin and mucous membranes are the primary loci of infection by staphylococcus and streptococcus, the extension to the blood or other parts of the body occurring only after the primary infection in the skin has been established. He concludes that cutaneous vaccination against staphylococcus and streptococcus with the antivirus filtrates has been shown to be a much more effective method of immunization than are the ordinary methods of subcutaneous or intramuscular injection.

Besredka reports the successful treatment by physicians, using wet dressings of antivirus filtrates, of such conditions as furunculosis, varicose ulcers, sycosis, boils, osteomyelitis, and pyoderma neonatorum, all caused by staphylococcus. Streptococcal infections also successfully treated were pleural fistula, pleurisy and puerperal sepsis. Success is also reported in ocular infections. The cases of puerperal sepsis were treated by uterine tampons soaked in antivirus filtrates and the eye infections by putting drops of antivirus in the eye.

Extending his theories to the enteric diseases, especially typhoid and dysentery, Besredka postulates that in these conditions the infecting organism has an "elective affinity" for the intestine. He states that numerous experiments have demonstrated that the localization of these organisms is always in the intestine irrespective of the mode of entry into the body. This, in our opinion, is open to question. In the experiments on dysentery in rabbits the Shiga bacillus was used. Here the effects of toxin formed by this organism seem not to have been sufficiently differentiated from the effects of the organism itself. There seems little justification for the view that the finding of organisms in the intestine after intravenous or subcutaneous injection is proof of their "affinity" for this organ. Furthermore, Besredka admits that infection of rabbits with typhoid or dysentery by the more direct oral route is difficult or impossible except when an intestinal irritation is set up by simultaneous administration of bile, or giving the cultures to fasting animals.

146. Flu, P. C.: Immunisation des rats contre la peste au moyen de suspensions concentrées de bacilles pesteux virulents lysés par le bactériophage anti-pesteux, Bull. Soc. path. exot. 26: 796-806, 1933.

Besredka cites a rather extensive series of observations on immunization against dysentery by the oral route in man and experimental animals. In rabbits and mice immunization was effected by feeding living or killed organisms in large amounts. In many cases such immunized animals were resistant to injection of toxin or organisms but had no demonstrable circulating antibodies. Vaccination of man by the oral route has also been tried in several epidemics of dysentery, particularly in Europe. Besredka reports one epidemic in which the incidence of disease in 546 individuals vaccinated by mouth was 7.6 per cent, while in 586 unvaccinated controls 40 per cent contracted the disease. In another epidemic among 1,768 nonvaccinated individuals there were fifty-six cases of dysentery as compared with twelve cases among 1,000 persons vaccinated by mouth. These results are less spectacular than those involving the smaller number of cases. Other examples of oral immunization are also cited by the author, but no comparisons with the method of immunization by injection of killed cultures or toxin-antitoxin mixtures are made.

Similar experiments on typhoid and paratyphoid infections in animals are cited by Besredka to support his theory of the affinity of these organisms for the intestine. Although infection of normal animals by the oral route with typhoid bacilli is impossible, Besredka and other workers cited by him have stated that oral immunization of animals against typhoid is readily effected. In rabbits immunity is readily established when bile is given along with either the living or the dead bacteria, but no immunity follows the ingestion of living cultures by animals not previously prepared by bile. Immunization by the oral route is said to be more rapid than that induced by injection.

Numerous examples of typhoid vaccination in man by oral administration of heat killed cultures and bile are cited by Besredka. These experiments compare immunization by oral bile vaccine, and by injected heat killed vaccine in several thousand individuals. The results cited indicate that the oral method of immunization is equal in effectiveness to the ordinary method of subcutaneous injection.

More recently, several investigators have reported both favorable and unfavorable results in the treatment of various diseases with antiviral. Haslé¹⁴⁷ attempted to treat typhoid with antiviral made from 25 day old cultures of typhoid organisms heated at 65 C. without filtration. Thirty-five patients given this preparation by mouth showed no effect. Intravenous injection of heated and filtered cultures in fifteen cases produced marked reactions with pyrexia, increased pulse and blood pressure, leukopenia, and relative increase in mononuclear cells. This was followed by a fall in temperature and relief of symptoms. There was only one death in the group of fifteen cases so treated compared with a prevailing mortality of 25 per cent. These results are almost identical with those observed in bacteriophage therapy and in nonspecific protein injections in typhoid. Kurzhals¹⁴⁸ reports favorable results in the treatment of furuncle of the external auditory meatus and ascribes the effect to a local and temporary immunity. Merten and Oesterlin¹⁴⁹ report favorable results of the antiviral treatment of malignant edematous infection in

one human case and in experimental animals. Their experiments indicate that the therapeutic and prophylactic effects observed are specific. Toennissen¹⁵⁰ has also reported the successful treatment of two cases of ulcerative colitis with staphylococcus-streptococcus-colon bacillus antiviral.

Space does not permit an adequate summary of Besredka's theory of local immunization. Stated briefly, the underlying idea is that the so-called receptive cells in the skin and mucous membranes or intestine are desensitized or made unreceptive to infection by contact with the bacterial vaccines or filtrates of autolyzed bacterial cultures. This desensitization of receptive cells is brought about, in part at least, by fixation on the cells of the hypothetical protecting substance, which Besredka calls antiviral.

Besredka's observations and theories have a bearing on bacteriophage therapy in two ways: first, if bacteriophage preparations contain the so-called antiviral, therapeutic effects might be expected from this substance as a result of local application or oral administration; second, immunization by local application to the skin or oral administration of vaccines has been shown to occur, and since bacteriophage preparations contain antigenic bacterial proteins they might be expected to have some immunizing effect when applied in the form of wet dressings or even when given by mouth.

In commenting on Besredka's treatment of staphylococcal and streptococcal skin infections with antiviral, Zinsser¹⁵¹ makes the following statement: "Attempts to confirm Besredka's claims as far as animals were concerned were unsuccessful in the hands of Mallory of our laboratory, who found that in staphylococcus infections in rabbits the uninoculated broth was as effective as the bacterial filtrate." In regard to Besredka's oral immunization procedures, Zinsser says: "In experiments carried out in our laboratory, the occasional immunizing properties of the feeding procedures, though irregular, were found to be true in principle, but we found it quite impossible to determine whether the occasional immunity obtained was due to true local immunization in the sense of Besredka or to a general immunization consequent on absorption from the bowel. The latter, which we believe was the case because of the development of agglutinins, would indicate that vaccination by mouth is nothing more than a very unreliable and quantitatively uncontrollable variant of subcutaneous injection." These and similar results of other investigators indicate that Besredka's ideas may not be well founded in fact.

SUMMARY AND CONCLUSIONS

1. Experimental studies of the lytic agent called "bacteriophage" have not yet disclosed its nature. d'Herelle's theory that the material is a living virus parasite of bacteria has not been proved. On the contrary, the facts appear to indicate that the material is inanimate, possibly an enzyme.

2. Since it has not been shown conclusively that bacteriophage is a living organism, it is unwarranted to attribute its effect on cultures of bacteria or its possible therapeutic action to a vital property of the substance.

3. While bacteriophage dissolves sensitive bacteria in cultures and causes numerous modifications of the

151. Zinsser, Hans: *Resistance to Infectious Disease*, New York, Macmillan Company, 1931.

organisms, its lytic action in the body is inhibited or greatly impeded by blood and other body fluids.

4. The material called bacteriophage is usually a filtrate of dissolved organisms, containing, in addition to the lytic principle, antigenic bacterial substances, products of bacterial growth and constituents of the culture medium. The effects of all these components must be taken into consideration whenever therapeutic action is tested.

5. A review of the literature on the use of bacteriophage in the treatment of infections reveals that the evidence for the therapeutic value of lytic filtrates is for the most part contradictory. Only in the treatment of local staphylococcal infections and perhaps cystitis (due to colon bacilli and staphylococci) has evidence at all convincing been presented.

6. There is no evidence that lysis or killing of bacteria by bacteriophage occurs *in vivo*, except possibly in the bladder and in walled-off spaces, where little exudate is present and where irrigation with large amounts of bacteriophage can be used.

7. The favorable results reported may have been due to the specific immunizing action of bacterial proteins in the material used and to nonspecific effects of the broth filtrates.

Therapeutics

THE THERAPY OF THE COOK COUNTY HOSPITAL

EDITED BY BERNARD FANTUS, M.D.

CHICAGO

NOTE.—In their elaboration, these articles are submitted to the members of the attending staff of the Cook County Hospital by the director of therapeutics, Dr. Bernard Fantus. The views expressed by various members are incorporated in the final draft for publication. The series of articles will be continued from time to time in these columns.—Ed.

THERAPY OF PAIN

"Next to the saving of life, the relief of pain is the physician's most important function." While it behooves the physician to be rather modest as to his ability of saving life, for the relief of pain he is well equipped. There is no pain that resists morphine; and there are so many other means of relieving pain that may be used instead of morphine—as the morphine may be worse for the patient than the pain—that there should be no case in which the physician well versed in therapeutics cannot give relief to pain and distress by properly chosen measures, not only without harm but with positive benefit to the patient. The patient has the right to expect relief of pain, for pain is in itself harmful, causing fatigue, insomnia, anorexia, depression of the circulation, psychic irritability and pessimism; and the longer pain continues, the more intolerant does one become of it.

From a teleologic point of view, pains are generally useful; from a therapeutic standpoint they rarely are. Pain may perhaps be said to be therapeutically useful when it commands immobility to a part that cannot be moved without possibility of harm, as in fractures of bones or in arthritis; but the physician should make this pain unnecessary by prompt and adequate immobilization. It is more frequently useful in diagnosis, as in acute appendicitis and in abdominal injuries in which

killing the pain may result in the patient's death because of obscuring the indications that may lead to a prompt life-saving operation. But even here it must be admitted that, the more expert the physician, the less need will he have of letting his patient suffer pain to find out what must be done for him. In most instances it is poor diagnostics as well as therapeutics to permit patients who have entered the hospital to suffer pain or distress for any length of time or until an elaborate history has been written and examination completed. The good physician should be expert enough to make reasonably adequate diagnosis promptly on admission in nearly all cases and sufficiently "therapeutic minded" to institute at once the necessary measures to make the patient more comfortable. One can get a better history and make a more satisfactory examination when the patient is not racked with pain.

Of course the mere removal of the perception of pain without taking care of the cause is often harmful to the patient. This is true not only of inflammatory and of traumatic conditions but also of those cases in which the pain or distress is a fatigue symptom. Merely relieving the pain and permitting the patient to go on with his work may lead to a catastrophe just as surely as removing a danger signal from a railroad track.

CAUSAL THERAPY

Causal therapy is therefore the prime desideratum. The pain of syphilis requires arsenic, also mercury, bismuth or iodine; malarial neuralgia indicates quinine. If, however, the causal therapy is not prompt in its pain relieving action, an analgesic should be given coincidentally.

In intrinsically obscure cases, in which causal therapy is impossible, relief of pain or distress is not only humane but also wise; for pain increases sensitiveness, which in turn makes the pain more agonizing. In such cases, nature may perfect the cure while the physician searches for the cause, keeping the patient comfortable in the meantime. When, however, a physician antagonizes a pain the cause of which is not clear, he must be honest in admitting (to himself) that he is merely practicing symptomatic therapy and he must ever sharpen his diagnostic methods and acumen so as to discover the real nature of the disease as well as to detect at the earliest possible moment when his temporizing treatment is harmful to the patient.

RESTORATIVE THERAPY

The physician should always try to understand the mechanism (pathology) by which the pain is produced and attempt to arrest or correct the departure from the normal by means of restorative therapy, which often also goes far toward relieving the pain. The "hunger pains" of peptic ulcer are promptly checked by neutralization of the gastric juice by food, alkali or mucin. In the pain of colics, atropine sulphate, from 0.5 to 1 mg., aids the effect of mere analgesics. So do the nitrites and the purines in the pains of angiospasm. Cold hydrotherapy, in addition to its intrinsic analgesic value, makes it possible, by the vasoconstriction that it produces, to secure relief of tension, pain being proportionate to tension. X-rays and massage, by favoring resolution of cellular infiltrations of recent origin, have analgesic values not adequately appreciated.

While thus aiming to cure pain by causal and by restorative therapy, one must not spurn its symptomatic relief. Pain being a trinity of psychic, physical and chemical nature, such relief is often best approached

from all these three sides simultaneously, though in certain cases any one of these may be the most important point of therapeutic attack.

PSYCHOTHERAPY

In the last analysis, pain is always psychic. Hence psychic measures must always be included in the stratagem of relief. There are a number of psychic vicious circles that may have to be broken in upon. For instance, pain creates anxiety, which concentrates attention on the affected part, and this increases the appreciation of the pain, for attention acts like a magnifying glass. Allaying anxiety in itself raises the pain threshold and makes possible the relief of pain with milder means than are required to annihilate the appreciation of a pain on which fear has fixed its watchful stare. This is how explanation and reasoning act on those whose mind is still accessible to reason. In those whom either their nature or the pain engendered panic has made incapable of reasoning, nothing but the potency of suggestion will allay the anxiety; and the physician who does not understand how and when to employ suggestion deserves to be defeated like the general who does not understand how to inspire his soldiers with the confidence of victory. Obviously, prompt and drastic relief of pain and distress has in itself a high degree of suggestive value.

The one form of pain best relieved by purely psychic means is psychalgia, which may be defined as pain perception without adequate physical or chemical causation. Such pain may be visualized as being due either to removal of the inhibitory control that the cerebral cortex exerts on the subcortical centers (e. g., the optic thalamus) or to an excessive irritability of the lower sensory neurons, so that sensations generally disregarded or merely spoken of as distresses become appreciated as pain. The diagnosis of psychalgia is suggested by absence or inadequacy of physical or chemical causes, by such stigmas of neurosis as unanatomic distribution of the pain, by the smiling avowal of "terrible" pain, as well as by the relief secured by purely psychic means. It is not admissible, however, to conclude merely on the basis of relief by psychic measures that organic causation is absent. At the most, such a result enables one to recognize a psychic contributing factor.

Psychoanalysis, in the widest sense, may enable one to recognize the symbolic nature of a pain; and the demonstration of this nexus may cure it. Grief may cause heart pain that may be mistaken for angina pectoris. Pain may be an escape mechanism, a way out of an intolerable situation; and the latter may have to be dealt with. Headache may mean "I don't want to do this." In pure psychalgia the ordinary treatment with analgesics and topical measures is a grave mistake. It merely fixes the patient's conviction of the presence of disease and focuses his attention on the treated part. "It is far easier to rub a disease into a patient's limb than to rub it out of the mind." The stratagem of neglect, which may be defined as paying no attention whatever to the complaining part while giving solicitous care to the patient as a whole, is frequently useful in psychalgias. One must ever beware of pathogenic suggestion, such as ascribing the pain complained of to a pathologic condition present but inadequate to cause the pain. Thus the diagnosis of a "tear in the womb" may make a psychalgia incurable by anything else but an operation or other adequate suggestion. Mere symptomatic relief of psychalgia, which is often easy, does not

suffice to prevent recurrence. It should be the starting point for psychic alternative therapy, for a program of mental hygiene.

Cases of psychalgia are so much more frequently encountered in private practice than in charity hospitals that experience merely in the latter does not quite qualify a doctor for complete success in the former. It has been well said that "the physician must be able to distinguish the patient who requires a pound of policy and an ounce of medicine from the patient who requires an ounce of policy and a pound of medicine."

MECHANOTHERAPY

(a) *Rest*.—As a general proposition, to which there are exceptions, pain indicates rest, especially those pains aggravated by movement. Such pain may be relieved and should be relieved by limiting that motion or making it impossible. This can often be accomplished by adhesive plaster or by light splints skilfully applied. The pain of inflammation, whether of traumatic or of infectious origin, is nature's way of enforcing rest, which is the first requisite for repair. By putting an inflamed part at rest, one not only relieves pain but also favors defense and repair. Whenever, by art, one cancels pain, one must also enforce the indicated rest by artificial means.

(b) *Posture*.—In many painful conditions, certain postures give a maximum of comfort and, as a general proposition, such postures should be secured. This may be elevation of a part to favor return circulation. It may be partial flexion of a joint to minimize tension. One must not, however, permit such a posture to continue unchanged for any great length of time, as then it becomes fixed and a possibly irremediable deformity may have been established.

(c) *Exercise*.—Prolonged immobility, even of a healthy part, renders resumption of motion painful. Hence mobilization should be started as soon as repair is well under way. At this time, movement may produce pain at first, but a continuance of the movement gives relief. In such cases the movement must at first be gentle and limited as to extent and time, so as not to traumatize tender tissue and lead to an acute inflammatory reaction. The fear should ever be present in the hospital physician's mind not to permit a patient to become permanently crippled, when he might have been saved from such a fate by appropriate mechanotherapy applied at the right time. The time and the place to apply physical therapy are generally while the patient is still in bed.

(d) *Massage*.—It is not sufficiently appreciated that massage has analgesic potency. Many a pain can be relieved by skilful rubbing. Of course, in traumatic and infectious inflammation a stage exists when the affected part must not be manipulated directly; but even here long centripetal strokes (effleurage) applied proximally to the area involved may have remedial potency by favoring drainage from and lessening tension in the affected part. This proximal effleurage is also employed as "introductory massage" to a part just recovering from acute inflammation, as the tissue thereby becomes more tolerant of direct manipulative attack. Preliminary induction of hyperemia also makes massage more acceptable and efficient.

Kneading (*pétrissage*): When tissue is squeezed, and especially when this squeezing is alternated with long centripetal strokes, there are sent onward into the return circulation fluid and other material that stagnated in the tissue; and, the valves preventing reflux, the

tissue thus treated becomes perfused with fresh arterial blood. One may visualize the effect of such maneuvers by thinking of the way in which, by squeezing it intermittently, one can greatly expedite the cleansing of a sponge immersed in water.

Friction, or a circular or elliptic movement of the overlying on the deeper tissues, is the important manipulation in the treatment of pathologic deposits remaining after the cause for their existence has subsided. It is a procedure intended to crush cellular deposits and to favor their dissipation without injuring the normal tissue; in other words, to disperse the products of inflammation. This would, of course, do harm as long as the inflammatory reaction serves to circumscribe or to fight infection. It is only when the infection has been overcome that it is permissible to attempt to clear away the débris from the battlefield more quickly and to favor prompter restoration to the normal by appropriate friction interspaced with pétrissage and effleurage. In a similar manner, absorption of a blood clot may be favored; but here also friction must not be employed too early, as it might lead to recurrence of the bleeding. A thrombosed vein should, of course, never be masséed for fear of causing embolism. It is most especially in neuralgia and in chronic myalgia that friction of the tender points or nodes is useful (nerve point massage, or "gelotripsy"). Even when friction is distinctly indicated, it may at first increase the pain; but this should shortly afterward diminish and the relief remain for quite some time thereafter. It is obvious that an understanding of pathology is required for the safe and efficient manipulative attack on abnormal tissue. Only a fully trained physician is competent to direct such treatment, and nurses should be able to administer it just as they are trained in the administration of medicines; for it is otherwise usually quite impossible for patients to receive the massage treatment at the time when it will do the most good. Whether the massage was properly applied or not may be judged by its results. Decrease of pain, of swelling and of stiffness indicates progress; increase in these means that harm has been done.

HYPEREMIA

Hyperemia is now known to have an analgesic value, and it is this knowledge that makes it possible to comprehend why so many apparently different therapeutic methods may be similarly useful in certain painful conditions.

(a) *Heat*.—Whenever there is pain, the application of heat is, next to rest, the most generally useful remedy. Whether one applies flannel or cotton wrapping, fomentations, poultices, the electric heating pad, the hot water bag, diathermy or radiant energy, the effect is essentially the same, though differing somewhat in detail of action and hence in special suitability for certain particular conditions.

Whenever there is superficial hyperesthesia, a warm covering has a soothing effect, whether it be wrapping the part in flannel or other poor heat conductor, or applying a poultice or a plaster. Belladonna Plaster has the additional analgesic value of the sensory nerve ending depressing effect of atropine. The hot water bag, the favorite domestic analgesic, suffers from the disadvantage of its weight, which may make it intolerable whenever there is much tenderness. The electric heating pad, fomentation and poultice are free from this objection. The last two mentioned are particularly indicated when the relaxing effect of warmth and mois-

ture favors a lessening of tension in the affected part: for, as stated before, pain is proportionate to tension. When relaxation of tissue is not demanded, radiant energy and most especially the incandescent light or the electric bowl heater may be the most convenient analgesic potency to be invoked. Pain in deep tissue may possibly be somewhat more effectively relieved by diathermy, but other methods of application of heat generally do quite as well. Whenever heat is employed, scrupulous care must be exercised against burns. At the conclusion of the treatment it is generally well to "fix the blood in the tissue" by a brief cold "finishing" procedure, the hyperemia "reaction" from which is much more lasting than is the hyperemia remaining after discontinuance of the heating procedure.

(b) *Counterirritation*.—The setting up of an inflammatory reaction in a healthy part of the body for the sake of affecting morbid processes elsewhere, which is

PRESCRIPTION 1.—*Rubefacient Pigment*

℞ Menthol	2.0 Gm.
Volatile oil of mustard	2.0 cc.
Alcohol	50.0 cc.

M. Label: Apply a few drops to affected area. (Must not be used in the vicinity of the eyes.)

the essence of counterirritation, while complex in its mode of action, owes part of its effect, no doubt, to the production of hyperemia. Counterirritants should never be applied to a part of the skin that is in a state of inflammation or that is liable to undergo morbid changes, as that exposed to roentgen therapy. There are two fundamentally different methods of counterirritation: that used with rubbing (liniments), and those used without rubbing (pigments, sinapisms, vesicants). In all cases the degree of irritation must be inversely proportionate to the sensitiveness of the part; a child's skin is more delicate than an adult's, a woman's skin more sensitive than a man's. The fair haired have a skin more easily damaged than that of the dark haired. The genitalia and the eyelids do not, of course, tolerate degrees of irritation that might be beneficial elsewhere.

Liniments: These, yielding a combination of the massage and hyperemia effects, which often reinforce

PRESCRIPTION 2.—*Cantharis Plasters*

℞ 6 Cantharis plasters	1 by 1 inch

Label: Oil the face of the plaster and apply in succession to tender points for about eight hours each.

each other, are contraindicated when massage is contraindicated; i. e., whenever there is danger of dissemination of pathogenic material, whether this is blood clot, micro-organisms, or tumor cells. While liniments are less efficient than is scientific massage preceded by the application of heat, they are often the only means practically available to procure this combination effect; and, when massage is indicated, even planless rubbing is generally better than no rubbing at all; and ordinary people can usually be made to rub a part more conscientiously when they are given something to "rub in."

The official Chloroform Liniment is probably as good as any other rubefacient liniment unless the powerful effect of mustard is desired, when the Compound Liniment of Mustard of the National Formulary might be preferred.

When rubbing is tabu, as in the presence of active infection, counterirritation without rubbing should be considered. Of these, painting the skin with Tincture of Iodine once or twice a day for several days (until the skin becomes chapped) is the simplest means of

securing the effect. In neuralgia, a 4 per cent solution of menthol and of volatile oil of mustard in alcohol applied as a pigment (prescription 1) may give relief. Sinapisms may have the advantage of better dosability when employed in the following manner: One part of mustard is mixed with an equal amount of flour or, for more delicate skin, with three or four parts of flour, and this is made into a paste with lukewarm water. The dough, spread over a backing, is covered with cheese-cloth and applied to the skin for from fifteen to thirty minutes. Reapplication may be ordered every eight hours and of a strength dependent on the previous reaction. If this is deficient, the application may be made stronger; if it is excessive or if the skin is still red from the previous application, a larger proportion of flour should be added. Vesication is indicated when rather lasting counterirritation is desirable in a chronic painful condition; and it is perhaps best secured by the application to the most tender points of a succession of

small (1 by 1 inch) Cantharis Plasters (prescription 2) for eight hours. These small blisters need not be opened and may simply be dressed with boric acid powder and sterile gauze kept in place by a cross of adhesive plaster.

PERIPHERAL SENSORY NERVE DEPRESSION

The most direct remedial attack on the diseased part being, in general, the most desirable, the consideration of local analgesia should logically take precedence over that of general analgesia. Pain may be checked by breaking in on the sensory nerve chain at any point between the place of production and the seat of its appreciation.

(a) *Local Anesthesia*.—This should be employed whenever possible. A minute drop of phenol on a tiny pledget of cotton packed into the cavity of a carious tooth temporarily relieves toothache, as if by magic. Mere application of a local anesthetic will check the

PREScription 4—Benzocaine Cerate

M. Label: Spread on gauze and apply to ulcer.

pain of raw surfaces. Cocaine, the most powerful of these, is by common consent taboo for this purpose because it is habit producing; and Ethyl Aminobenzoate (benzocaine, anesthesine) may be considered a representative of the least objectionable agents of this kind to be applied to painful raw surfaces; e. g., as an oil compress (prescription 3), possibly best dissolved in camphorated oil, which is in itself useful on gauze as a dressing, packing or drain in lacerated and in suppurative wounds. In painful ulcers with minimal discharge, a benzocaine cerate (prescription 4) might be useful.

The ethyl chloride spray, which has the double effect of producing local anesthesia followed by prolonged hyperemia, is easily applied, cleanly, and in appropriate cases quite efficient, especially in neuralgias.

Injection anesthesia, to be employed when the skin surface is unbroken, might be secured by procaine, which in 1 per cent solution might be used in quantities up to 40 cc. in the form of encircling infiltration; i. e., injection into the area surrounding an inflamed organ

but not into the inflamed tissue itself. Arthritic joints may be made painless by pushing the needle's point into the fascia surrounding the joint, but not into the capsule or the joint itself. The pain of hyperalgetic irradiation, such as that accompanying visceral disease, may be temporarily relieved by intradermal infiltration with procaine solution of the skin overlying the area where the pain is most intense, taking care to produce a well defined wheal of possibly 3 cm. diameter and avoiding injection into the subcutaneous tissue. A quantity of

from 2 to 4 cc of 2 per cent procaine solution generally suffices for this purpose.

Paravertebral blocks by means of possibly 10 cc of 0.5 per cent procaine solution is probably not employed as frequently as it deserves to be for diagnosis as well as treatment in severely painful visceral conditions, such as biliary or renal colic, angina pectoris or the crises of locomotor ataxia. Paravertebral block of the sympathetic nerves is also useful for relief of pain in the extremities in such conditions as Raynaud's disease, thrombo-angiitis obliterans and arteriosclerotic claudication.

Nerve destruction, most especially by means of 95 per cent alcohol injection preceded by local anesthesia with 2 per cent procaine solution, should be employed

PREScription 6—Analgesic Pigment

more frequently than it is in intractable chronic painful conditions, not only in trigeminal neuralgia and in sciatica but also in inoperable carcinoma. For the latter condition this procedure or, if the relief secured is too transient, surgical nerve section might dispense with the necessity, otherwise generally present, of making the sufferer a victim of morphinism.

(b) *Local Analgesia*.—The fact that lessening the irritability of the superficial expansion of nerves diminishes also the appreciation of deep pain is made use of not only in the form of local anesthesia but also in the application of local sensory nerve depressants that act percutaneously, such as aconite and belladonna, e. g.,

PREScription 7.—Potassium Bromide

R Potassium bromide, 30.0 Gm
Water 15.0 cc
Syrup of raspberry, to make 120.0 cc
M Label Teaspoonful in water (or milk, especially in the under-nourished) after meals and at bedtime. (Contraindicated in patients suffering from acne Watch for bromoderma)

in the form of A. B. C. liniment (prescription 5). When massage is contraindicated, a pigment composed of camphor, chloral and menthol (prescription 6) might be of use.

(c) *Cold Applications*.—These are of limited analgesic value, of possibly special applicability in deep-seated inflammatory conditions (excepting in rheumatism and in nephritis, in which conditions cold procedures are generally contraindicated). Thus the ice cap is put into requisition with the hope of diminishing acuteness of the pain produced by congestion or inflammation of the intracranial structures. In peri-

carditis the tendency of the ice bag to slow the pulse may possibly be the more important factor; in appendicitis it may be the necessity of lying perfectly still when one balances an ice bag on the abdomen. The slight degree of the penetration of the cooling effect makes cold applications relatively safe in deep-seated infections. In more superficial infections it is probably presumptuous to apply cold, for how can one tell when the inflammatory reaction is excessive? In contusions, cold applications may bring comfort; but they should certainly not be applied when there is danger of necrosis. Very hot or very cold applications or strong chemicals may cause the death of tissue hovering between life and death, which might have survived more physiologic treatment.

(d) *Roentgen Therapy*.—This relieves pain due to pressure on or tension within nerves by lesions, the involution of which these rays are capable of causing. Frequent small doses of x-rays are used to relieve pain in some of the far advanced malignant conditions. Thus, in carcinoma of the prostate with metastasis to

the spine they are of some help. They are also used to relieve pain in inflammatory lesions about the nerve roots, the most noteworthy example of which is herpes zoster.

CENTRAL ANALGESICS

Central analgesics need be resorted to most especially in pains of general dissemination, a distribution that should also lead to search for a general cause and its treatment. To estimate the degree of pain and the degree of analgesia that will probably be required to relieve it, one should arrive at an estimate of the patient's general sensitiveness. The following simple test may be of some help for this purpose: Pressure with the thumb against the tip of the normal mastoid bone generally elicits no pain, while pressure against the styloid process generally does. In the hyposensitive individual neither pressure excites pain, while in the

PREScription 9.—*Carbromal and Phenobarbital*

Label: One after meals and at bedtime.

hypersensitive both pressures do. A "severe" pain in a hypersensitive individual will respond to much milder remedies than will be required to relieve a severe pain in a hyposensitive patient.

(a) *General Sedatives*.—Hypersensitiveness as well as general algæsia ("pains all over") suggest bromide as at least a part of the therapeutic program. This is probably best disguised by Syrup of Glycyrrhiza (see Insomnia, prescription 1); but Syrup of Raspberry (prescription 7) may be more palatable to some; and it looks less "medicinal." Carbromal (prescription 8) and this in combination with phenobarbital (prescription 9) represent two higher degrees of sedation if that obtainable from bromide is inadequate. One should always inquire whether the pain interferes with sleep, not only because such pain is more likely to be of anatomic rather than of functional origin (fatigue pains do not interfere with sleep) but also because the additional use of a hypnotic (in sleep-compelling doses, see Insomnia) may be advisable to prevent the development of insomnia-induced nervous hyperirritability.

(b) *The Coal Tar Analgesics*.—These agents are effective against functional (neuralgic) pains rather than against those of organic (e. g., traumatic) causation. Before prescribing such purely symptomatic analgesics, one should determine whether the pain is continuous or intermittent. For the latter form the analgesic would be taken merely "as required." Acetanilid is the least expensive of these agents and when used with care perhaps as safe as any of them. When several 0.2 Gm. tablets of acetanilid or 0.3 Gm. tablets

PREScription 10.—*Antipyrine*

(Price index, 12: the approximate price per dose as compared with acetanilid, 1.)

of acetphenetidin given at intervals of two or three hours fail to relieve, larger doses should not be given, because they will probably also prove ineffective and might be toxic. A maximum daily dose of 1.5 Gm. of acetanilid should not be exceeded. Amidopyrine in doses of 0.3 Gm. (tablets) given every two to four hours has been the favorite analgesic of this group. In view of recently accumulating evidence that this agent may be followed by neutropenia, it should probably not be employed without preliminary and occasionally repeated control of the neutrophil count. Its maximum single dose has been placed at 1 Gm. and the day's dose at 3 Gm. While these three first-mentioned substances are too insoluble to be suitable for administration in

any other than solid dosage form, antipyrine (0.3 Gm.) is the one agent of this group that should be always administered in liquid dosage form, well diluted, as it, like other very soluble bodies, may produce gastric irritation when given in solid dosage form. Its taste is not easily disguised: peppermint (prescription 10), or Syrup of Citric Acid (lemon) having been variously recommended. It might be given in suppository form (prescription 11). Whenever antipyrine is administered, one must look out for skin eruptions that might be produced by it.

(c) "*Antirheumatics*".—Probably all sedatives are more or less antiphlogistic, i. e., have a tendency to lessen the degree of inflammatory reaction. It may be

PREScription 12.—*Acetylsalicylic Acid with Hyoscyamus*

Rx Extract of hyoscyamus 0.15 Gm.

Mix and divide into fifteen capsules.
Label: One every hour until relieved, then every two to four hours as required.

that this effect is particularly prominent in the salicylates and in cinchophen, both of which have quite a vogue in the treatment of "rheumatic" pains, which might perhaps be more appropriately called the pains of "fibrositis," whether this nonsuppurative inflammation affects joints, muscles or nerves. While in rheumatic fever sodium salicylate is the remedy of greatest effect, acetylsalicylic acid (price index, 4), being somewhat more analgesic, is generally preferred in doses of 0.3 Gm. (tablets) every hour until the pain is relieved, then every two to four hours in other less acute fibrositic painful conditions. Its chief untoward effect is its

tendency to produce excessive sweating, which might be somewhat antagonized by a drug of the belladonna group; e. g., Extract of Hyoscyamus (prescription 12). Neocinchophen (price index, 97), which is less likely to produce diaphoresis than acetylsalicylic acid, might be preferable were it not for its high cost and for the suspicion that it may produce acute yellow atrophy of the liver. This danger is not nearly as great with neocinchophen as it is with cinchophen, the use of which

PRESCRIPTION 13.—Morphine Sulphate for Injection

R Diluted hydrochloric acid.....	0.05 cc.
Morphine hydrochloride.....	0.10 Gm.
Distilled water.....to make	10.00 cc.

Place in multiple dose ampule and sterilize.

Label: 1.0 cc. equals morphine 0.01 Gm. For hospital purposes, multiple dose ampules are much more economical and convenient than are hypodermic tablets. The addition of a small quantity of hydrochloric acid serves to stabilize the solution.

should be entirely abandoned. Neocinchophen should not be employed in patients with hepatic or biliary diseases or in patients with fever; in any case it should not be used continuously for more than three days at a time.

(d) *Opiates*.—There is no pain that resists morphine given by injection. If shock is present and severe, it should be administered by slow intravenous injection, as otherwise its effect would be late in asserting itself, which might lead one to piling on of a toxic dose before the effect can be secured. Ordinarily, hypodermic injection suffices (prescription 13). When facilities for injection are not available, sublingual administration of a crushed "hypodermic" tablet will give quicker response than swallowing the dose. In the presence of excruciating pain of acute disease, it is inhumane to experiment with other analgesics. The dose of morphine sulphate may be placed at 15 mg. for a man and 10 mg. for a woman. This dose may be repeated once in from one-half to one hour, if the pain has not been sufficiently relieved. After this a dose every four hours usually suffices to maintain the effect. Infants should not get morphine. To small children, not more than 1 to 2 mg. of morphine should be given; to children of school age, not more than from 2 to 4 mg. at a dose. Morphine is contraindicated by the presence of cyanosis,

PRESCRIPTION 14.—Acetanilid-Acetylsalicylic Acid Compound

R Extract of hyoscyamus.....	0.15 Gm.
Acetanilid.....	1.00 Gm.
Acetylsalicylic acid.....	5.00 Gm.

Mix and divide into fifteen capsules.

Label: One every two to four hours as required.

unless this is due to pleuritic pain. It is also positively contraindicated in all chronic painful conditions, unless they are malignant. In jaundice its use should be avoided, as it may cause itching or increase it.

Combinations of morphine (10 mg.) with atropine (0.5 mg.) is especially indicated in the pain of colics. Such a combination is also believed to lessen some of the untoward effects of morphine. To minimize the disagreeable after-effects of morphine, one might give every four hours, for several doses, one half of each previous dose. Hot black coffee, a laxative, and maintaining the recumbent posture for some time after awakening from the morphine sleep are also helpful.

While codeine is decidedly less habit producing than is morphine, it is a much feebler analgesic and it is also relatively much more expensive than morphine. As codeine is probably only about one tenth as efficient in relieving pain as morphine, it may cost ten times as much to secure the same effect. In a hospital in

which the patient is under complete control, its use for the relief of pain is therefore rather uneconomical.

(e) *Combination Analgesics*.—The validity of Bürgi's rule that "agents producing the same effect in different ways mutually increase their efficiency" is well illustrated by the analgesics. While there would be no sense in prescribing acetanilid with acetphenetidin, combining acetanilid with acetylsalicylic acid is likely to enhance the analgesic value but also the sudorific effects. This might be antagonized by extract of hyoscyamus (prescription 14).

While polypragmasy, the irrational combining of too many different remedies at one time, is just as objectionable as is polypharmacy (the shotgun prescription), there is validity—at least in private practice—in the maxim that "whenever possible, the physician should apply a local remedy; for if he does not, some one else will, and he may not do it as wisely." There is also wisdom in the old preceptor's advice: "Prescribe a box and a bottle"; the one intended for symptomatic relief to be used as required, the other remedy to produce more fundamental modifications, causal or restorative, so as to make recourse to the symptom remedy progressively less necessary.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY OF THE AMERICAN MEDICAL ASSOCIATION HAS AUTHORIZED PUBLICATION OF THE FOLLOWING ARTICLE.
H. A. CARTER, Secretary.

EDUCATION IN PHYSICAL THERAPY IN THE STATE OF PENNSYLVANIA

FRANK H. KRUSEN, M.D.

PHILADELPHIA

Although, in certain centers, the practice of physical therapy has made remarkable strides during the past five years, widespread knowledge of the subject is still lacking. Elbert Hubbard has said: "A man is usually down on that which he is not up on." Education in physical therapy has progressed sufficiently so that the rank and file of physicians have gained sufficient knowledge of the subject to be no longer blindly antagonistic to physical therapy as a whole. Molander¹ has said: "There is lack of appreciation as to the vastness of the field of physical therapy. It ramifies through every phase of medicine."

Shaul² has pointed out that "the attempt to evaluate physical therapy as a whole should be abandoned"; that it is just as difficult to answer the question "What do you think of physical therapy?" as it is to answer the question "What do you think of radiology?" or "What do you think of internal medicine?"; that "if a distinction exists outside the minds of the uninformed, it is that physical therapy requires a more detailed knowledge of physical agencies." Physicians are now learning that there are many simple physical measures which are applicable to general practice. Gaenslen³ has pointed out that "90 per cent of the necessary work . . . so far as physical therapy is concerned can be accomplished by exercises, massage, muscle training,

1. Molander, C. O.: Physical Therapy in Teaching Hospitals, J. A. M. A. 96:1879 (May 30) 1931.

2. Shaul, E. M.: What Do You Think of Physical Medicine? Arch. Phys. Therapy 14:105 (Feb.) 1933.

3. Gaenslen, F. J.: Who Should Teach Physical Therapy? J. A. M. A. 100:1435 (May 6) 1933.

and posture work with no other equipment than can be found in the ordinary home." One might add that all that is needed is the general training of physicians in the use of such simple physical measures. Gaenslen concludes: "We are too apt to think of physical therapy in connection with injuries when as a matter of fact there is a large field for this branch of therapy in internal medicine and in general surgery as well as in the specialties."

The channels through which medical education in physical therapy has been and still further should be developed are:

1. The premedical teaching.
2. The undergraduate medical teaching.
3. The graduate medical teaching.
4. The teaching hospitals.
5. The state and county medical societies.
6. The medical journals.

Advances have been made through all these channels; much must still be accomplished, however, before the average physician can be trained in the routine use of the many valuable and simple physical measures now available for the treatment of disease.

In premedical teaching, more satisfactory courses in truly medical physics are being established to replace the courses previously offered, which were primarily of value to the engineering student. At least one premedical school in Pennsylvania is doing this, and others will probably follow.

In undergraduate medical teaching, courses in physical therapy (which is really applied premedical physics) are now being conducted. In Pennsylvania, five of the six medical schools are giving more or less complete courses in physical therapy to undergraduate medical students.

There are two vicious circles that handicap the development of physical therapeutic teaching in Pennsylvania as in other states.

(a) There is an inadequate number of trained instructors because the schools have failed to teach physical therapy; and the schools have failed to teach physical therapy because there is an inadequate number of instructors.

(b) The present organizers of medical curricula are for the most part unacquainted with physical therapeutics and hence have failed to include it in their program. As the students of the present become the curriculum makers of the future, we have a vicious circle.⁴

For these reasons, progress has been slow; nevertheless, definite steps forward in undergraduate teaching have been noted.

There are now organized, at certain medical centers, a few adequate graduate school courses for physicians who desire to specialize in this field, as well as shorter introductory courses for general practitioners who desire a brief working knowledge of the subject. These schools, however, are not readily available to all physicians.

Although slow but steady progress is to be seen in institutional education in physical therapy, there is still a very great need for postgraduate education "outside of teaching institutions."

In its most recent report,⁵ the Committee on Education of the Council on Physical Therapy says:

The committee believes that this is the field which best lends itself to early development and that furthermore there is here

a greater necessity for immediate action than under the other heads. The Committee on Education is fully cognizant of the fact that adequate education in this field of therapy can be brought about only by long range planning in respect to undergraduate education as a whole. This point is axiomatic and emphasis made in another direction is not to be interpreted as failure to visualize the fundamental need.

The situation as regards the use of physical therapy among the practicing profession as a whole throughout the United States is, however, nothing short of deplorable. Large sections of society are at present wholly without advice, not to say practical assistance, concerning measures which often spell the difference between invalidism and health. This fact is perhaps best illustrated in terms of injured or diseased joint structures but has almost equal application in a wide range of other medical and surgical conditions. The committee thoroughly appreciates that it is futile to expect an adequate grasp of the field of physical therapy on the part of the profession as a whole during the lifetime of the present generation, but it is equally satisfied that much can be done to improve conditions as they now exist.

This is undoubtedly true; and it is equally true that the profession is eager to receive instruction in this field. This is manifested by the manner in which, in the past, physicians have flocked to poorly organized commercial courses on the subject. Concerning these courses, Molander¹ wrote in 1931:

There are many short courses given by commercial concerns which naturally emphasize the products they sell. Such courses give one a decidedly wrong impression of the entire field. However, such courses cannot be condemned as much as the shortsightedness of medical schools and teaching hospitals in not making available adequate instruction in physical therapy.

Because of the work of the Council on Physical Therapy, and partly because of the establishment of more satisfactory, well balanced, authoritative and conservative courses by medical societies, a ruling was made by the American Medical Association which refuses the acceptance of advertising from commercial firms that offer such courses.

The Committee on Education of the Council on Physical Therapy has expressed the belief that "tangible and useful results" may be obtained by well organized courses of instruction given by state and county societies. It cites the very successful course given by the Philadelphia county society four or five years ago and the "subsequent more extensive activities in New York State." Still more recently, Kovacs⁶ has mentioned that "a five day seminar was held, under the auspices of the Committee on Education of the Philadelphia County Medical Society" and that "the entire series of these lectures was published in book form." This seminar, held in April 1932, gave startling proof that practicing physicians were eager for good instruction in physical therapy, since, "to the surprise of the committee, over 400 physicians registered for the course—over 60 physicians attended the course from parts of Pennsylvania outside of Philadelphia. In addition, there were 2 registrants from California, 2 from Delaware, 1 each from Florida, Illinois, Kentucky and Missouri, 8 from New Jersey, and 1 from Wisconsin."⁷ One registrant wrote: "I spent a profitable and enjoyable week, missing but one lecture, and have now some clear ideas about physical medicine, where before I was hopelessly confused."

Subsequently, a similar seminar was presented in Pittsburgh.

4. Krusen, F. H.: Teaching of Physical Therapeutics in the Medical School Curriculum, *Arch. Phys. Therap.* 14: 154 (March) 1933.

5. Unpublished report of the Committee on Education of the Council on Physical Therapy of the American Medical Association.

6. Kovacs, Richard: Physical Therapy Committees in State and County Medical Societies, *J. A. M. A.* 102: 1296 (April 21) 1934.

7. Pennsylvania Seminar on Physical Medicine, editorial, *Arch. Phys. Therap.* 13: 434 (July) 1934.

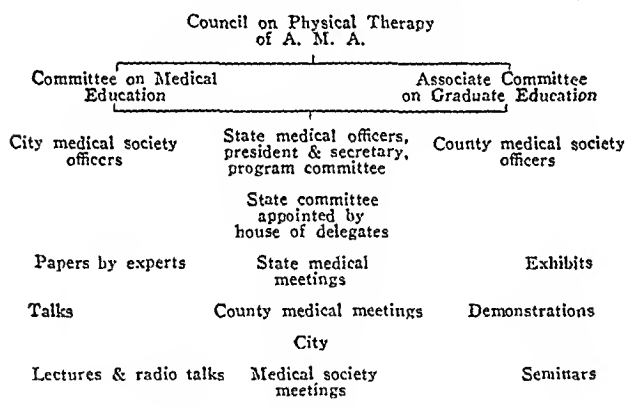

There is no reason why every county society in the country cannot present such a seminar, suiting its program to the local needs, so that throughout the United States physicians now "hopelessly confused" may gain some "clear ideas" concerning physical therapy. What is needed at present is a guiding hand: the coordinated effort of an interested group of informed physicians in each state to organize such instruction and to bring it to the physicians who have so earnestly demonstrated their desire to have it. With this thought in mind, the following resolution has been presented to the state secretary for introduction to the house of delegates of the Medical Society of the State of Pennsylvania:

Resolved, That the House of Delegates of the Medical Society of the State of Pennsylvania consider the appointment of a special committee on physical therapy, the duties of which will be to promote graduate education in physical therapy in the state of Pennsylvania.

Such committees have already been appointed in New York, California and Illinois.

Kotkis⁸ has suggested a scheme of organization for the advancement of education in physical therapy, as follows:

*Scheme of Organization for Advancement of Education
in Physical Therapy*

Kovacs⁹ has already offered "an outline of organization and plan of activities" for physical therapy committees in state and county medical societies. The Council on Physical Therapy now proposes to organize an associate committee "to promote graduate education in physical therapy."

The possibilities have been demonstrated. All that is required at present is cooperative action in promoting instructional courses at regular county and state medical society meetings throughout the land, instead of at a few isolated meetings.

Finally, much might be done to promote rational training in physical therapy by obtaining the cooperation of the editor of each state medical journal in establishing a column on physical therapy. The *Pennsylvania State Medical Journal* has done this successfully. Just as the Council on Physical Therapy has published a series of sanctioned authoritative articles on various phases of physical therapy in the columns of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, so might each state journal publish a briefer, committee-sanctioned column on more fundamental phases of physical therapy.

REPORTS OF THE COUNCIL

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION
OF THE FOLLOWING REPORTS. H. A. CARTER, Secretary.

NOTICES OF REACCEPTANCE

The Council on Physical Therapy has reaccepted the following devices and products for a period of three years:

DAVIS INHALATOR. Manufacturer: Davis Emergency Equipment Company, Inc., New York. A resuscitation apparatus designed to assist in the administration of oxygen or a mixture of oxygen and carbon dioxide in various forms of asphyxia. Recommended for suffocation due to drowning, electric shock and gas poisoning.

UVIOL-JENA ULTRAVIOLET TRANSMITTING GLASS. Manufacturer: Schott & Gen., Jena. Distributors: Fish-Schurman Corporation, New York. A window glass for transmitting a portion of the biologic ultraviolet rays of the sun or other source.

NATIONAL VAPORIZERS, TYPES 1 AND 2. Manufacturer: The National Drug Company, Philadelphia. A device for vaporizing oil or aqueous solutions.

VICTOREEN r-METER. Manufacturer: Victoreen Instrument Company, Cleveland. An instrument for determining the intensity of roentgen rays at any point in the field in roentgens per minute.

FRICKE-GLASSER X-RAY DOSIMETER. Manufacturer: Victoreen Instrument Company, Cleveland. An instrument designed to measure the quantity and intensity of roentgen rays and calibrated in international roentgens.

REQUIREMENTS FOR ADVERTISING OF ABDOMINAL BELTS, CORSETS, AND SPECIAL SUPPORTS

The Council on Physical Therapy has adopted the following minimum standards for acceptance and policy pertaining to the selling and advertising of abdominal belts, corsets, and special supports recommended for therapeutic use.

- I. Misleading claims concerning the structure, material, workmanship, etc., will warrant rejection of the product.
- II. Acceptance or rejection of such products will be based in a large measure on the advertising claims of the manufacturer and on the therapeutic evidence presented. In advertising either to the public or to the profession, the following therapeutic claims are acceptable to the Council:

- A. Such products form a satisfactory method of support in certain individuals with large pendulous abdomens.
- B. Similar supports may be used in the case of large pendulous breasts.

- III. In advertising solely to the profession, manufacturers may use the additional therapeutic claims as follows:

- A. In pregnant women, where abdominal or pelvic support is needed.
- B. In cases of hernia, where support is needed.
- C. In certain definite displacements of abdominal viscera, where support is needed.
- D. In selected cases of weakness of abdominal walls, due to infantile or other forms of paralysis where support is needed.
- E. In selected cases of defective posture in connection with corrective exercises or other treatment.
- F. In selected cases of low back pain where support is needed.
- G. In selected cases of circulatory disturbances of the extremities, where support is needed.
- H. In occasional cases after laparotomy where support is indicated.
- I. In occasional cases of injury to the extremities where support is needed.

- IV. In the past, it has been customary for certain manufacturers or distributors to rebate to physicians desiring it a certain percentage of the selling price of these devices. This is definitely incompatible with medical ethics. The Council, therefore, will reject any devices sold by manufacturers who persist in this practice.

The foregoing standards apply to those manufacturers who limit the sale of their devices to direct advertising to the public and to the profession. The Council can accept these devices

8. Kotkis, A. J.: Personal communication to the author.

when any firm agrees so to limit its advertising and agrees not to use sales agents or to sell directly to the public. In the case of those manufacturers who employ demonstrators in department stores and saleswomen canvassing the devices from door to door, who use exaggerated statements for the purpose of consummating a sale, which cannot be checked or controlled either by the manufacturer or by the Council, it must be the policy of the Council that such devices cannot be accepted. The Council refuses to assume the responsibility of furthering any questionable sales methods by allowing such manufacturers or their agents to say that "this article is accepted by the Council on Physical Therapy of the American Medical Association."

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary.

DIPHTHERIA TOXOID, ALUM PRECIPITATED (REFINED) (See New and Nonofficial Remedies, 1934, p. 393).

Eli Lilly & Co., Indianapolis.

Diphtheria Toxoid, Alum Precipitated (Refined) Lilly—Prepared from diphtheria toxin by treatment with formaldehyde and precipitated with alum, washed, and resuspended in physiologic solution of sodium chloride. The product is tested for antigenic efficiency as prescribed by the National Institute of Health: guinea pigs weighing 500 Gm., given one human dose, must produce at the end of six weeks at least two units of diphtheria antitoxin in each cubic centimeter of blood.

It is marketed in packages of one immunization treatment, containing one 0.5 cc. vial, and in packages of ten immunizations, containing one 5 cc. vial of the refined toxoid.

SULPHARSPHENAMINE-ABBOTT (See New and Nonofficial Remedies, 1934, p. 82).

The following dosage forms have been accepted:

Sulpharsphenamine-Abbott, 0.1 Gm. Ampules.

Sulpharsphenamine-Abbott, 0.5 Gm. Ampules.

Sulpharsphenamine-Abbott, 0.8 Gm. Ampules.

SCILLONIN (See THE JOURNAL, Dec. 1, 1934, p. 1708).

The following dosage form has been accepted.

Coated Tablets Scillonin, 0.5 mg.

INSULIN-STEARN'S (See New and Nonofficial Remedies, 1934, p. 225).

The following dosage form has been accepted:

Insulin-Stearns, 100 Units, 10 cc Each cubic centimeter contains 100 units.

DIPHTHERIA TOXOID (See New and Nonofficial Remedies, 1934, p. 390).

Wm. S. Merrell Co., Cincinnati.

Diphtheria Toxoid—Prepared from diphtheria toxin the L+ dose of which is 0.2 cc or less by treatment with formaldehyde solution at a temperature of from 38 to 40 C. until its toxicity is so reduced that injection of five maximum human doses into guinea pigs causes no local or general symptoms of diphtheria poisoning. The product is tested for antigenic potency by injection into at least ten guinea-pigs of one human dose each; if at the end of six weeks at least 80 per cent of the animals survive for ten days the injection of five minimum lethal doses of diphtheria toxin, the toxoid is considered satisfactory. Marketed in packages of two 1 cc. vials, and in packages of fifteen immunization treatments of one 30 cc. vial.

DIPHTHERIA TOXOID, ALUM PRECIPITATED (REFINED) (See New and Nonofficial Remedies, 1934, p. 393).

Wm. S. Merrell Co., Cincinnati.

Diphtheria Toxoid, Alum Precipitated (Refined)—Prepared from diphtheria toxin the L+ dose of which is less than 0.2 cc. The toxin is detoxified with an appropriate amount of formaldehyde solution so that the injection of five human doses, subcutaneously, into guinea pigs causes neither general nor local symptoms of diphtheria poisoning. The toxoid is refined by precipitation with a sterile solution of potassium aluminum sulphate. The precipitate is then washed with sterile physiologic solution of sodium chloride and resuspended in sufficient physiologic solution of

sodium chloride to bring its volume to that of the toxoid from which the precipitate was prepared. The finished product is preserved with merthiolate, 1:10,000, and contains less than 2 per cent of alum. The product is tested for antigenic potency by the method prescribed by the National Institute of Health: the human dose must produce in guinea pigs within six weeks at least two units of diphtheria antitoxin per cubic centimeter of blood serum. It is marketed in packages of one 1 cc. vial (one immunization) and one 10 cc. vial (ten immunizations).

TYPHOID VACCINE (See New and Nonofficial Remedies, 1934, p. 398)

Wm. S. Merrell Co., Cincinnati.

Typhoid Vaccine—A suspension of killed typhoid bacilli in physiologic solution of sodium chloride, preserved with 0.5 per cent of phenol. The product is prepared according to the method of the U. S. Army Medical School from the Rawling's strain. Marketed in packages of three vials, the first containing 500 million killed typhoid bacilli in 0.5 cc. of suspension and the second and third containing 1,000 million killed typhoid bacilli in 1 cc. of suspension, in packages of one 5 cc. vial containing 1,000 million killed typhoid bacilli per cubic centimeter, and in packages of one 20 cc. vial containing 1,000 million killed typhoid bacilli per cubic centimeter.

DIPHTHERIA IMMUNITY TEST (SCHICK TEST) (See New and Nonofficial Remedies, 1934, p. 404).

Wm. S. Merrell Co., Cincinnati.

Diphtheria Toxin for the Schick Test, Diluted with Peptone Solution and Ready for Use—A diphtheria toxin made by growing diphtheria bacilli in broth, aging and diluting with peptone solution according to Bunney (*J. Immunol.* 20:71 [Jan.] 1931). The product is ready for use, no diluent being required. The diluted toxin is of such strength that 0.1 cc. (one dose) given intradermally constitutes one fiftieth minimum lethal dose for a guinea pig of 250 Gm. weight. Marketed in packages containing sufficient material for 10 and 100 tests.

REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT

PAUL NICHOLAS LEECH, Secretary.

ACIDOPHILUS BACILLUS LIQUID-MULFORD AND MULFORD ACIDOPHILUS BACILLUS BLOCKS OMITTED FROM N. N. R.

Acidophilus Bacillus Liquid-Mulford and *Mulford Acidophilus Bacillus Blocks*, manufactured by Sharp & Dohme, Inc., were accepted for inclusion in New and Nonofficial Remedies in 1930 and 1929, respectively. The former is:

"A whey culture of *Bacillus Acidophilus* (Moro) in a whey medium. It contains 50 million viable organisms per cubic centimeter at the time of sale."

The latter is:

"A culture of *B. acidophilus* (X strain), embedded in a 2 per cent agar jelly containing milk powder, lactose, *D*-glucose and sucrose, and marketed in the form of chocolate covered cubes, each of which contains approximately 150 billion viable organisms (*B. acidophilus*) at the time of issue."

The Council is now considering the evidence for the therapeutic value of *acidophilus bacillus* preparations in general, and all the accepted brands for the present have the status of being accepted for one year only instead of for the usual three year period. In considering the material submitted by Sharp & Dohme, Inc., for the limited reacceptance of the two products named in the last paragraph, the referee found that these were not being marketed in accordance with the Council's requisites for such products. The firm was informed of this in each case and has not taken steps to make the products eligible for reacceptance. It appears that both products are considerably inferior to the Council's requirement that accepted preparations contain not less than 200 million viable *B. acidophilus* organisms at the time of manufacture and at least 100 million at the date of expiration (New and Nonofficial Remedies, 1934, p. 252). The Council's referee reported on each product as follows:

Acidophilus Bacillus Liquid-Mulford

The last period of acceptance of this product expired at the end of 1931. In November 1931 the Council voted to reaccept this product provided the firm (a) submitted labels bearing the date of manufacture, date of expiration and number of living

organisms per cubic centimeter, (b) prepared a product containing at least 100 million viable organisms per cubic centimeter at the expiration date, in accordance with the standards adopted by the Council, and (c) revised its circulars, pamphlets and labels by omitting specific use of the terms intestinal toxemia, toxic conditions due to intestinal putrefaction, and terms of this nature. This report was sent to Sharp & Dohme, Inc., Dec. 4, 1931.

In March 1932 the firm replied, sending labels, cartons and circulars which were found to be unsatisfactory because they lacked the statements required and did not indicate that the product would contain at least 100 million viable *B. acidophilus* organisms at the expiration date. In order to place this product on the same basis of acceptance as the other *Bacillus acidophilus* products, the Council voted in June 1932 to reaccept *Acidophilus Bacillus Liquid-Mulford* for a period ending Dec. 31, 1934, provided the firm made the indicated revisions in the labels, cartons and circulars, reduced the expiration period to one month unless evidence was submitted showing that a longer expiration period could be truthfully claimed, and improved the product so that it would contain 100 million viable *B. acidophilus* organisms at the expiration date.

On Feb. 13, 1934, Sharp & Dohme, Inc., replied to a letter of Dec. 18, 1933, from the secretary and sent in the current labels, cartons and circulars used for *Acidophilus Bacillus Liquid-Mulford*. At the same time there was forwarded to the Council a copy of a memorandum from the director of the firm's biologic laboratories stating his belief that the labels and advertising were in accordance with the requirements of the Council, that "the product invariably comes through with an original count of 1,000 million bacilli per cc., but a great deal of variation occurs in the keeping qualities of the individual lots regardless of time and temperature." He expressed satisfaction with the product and stated that in view of "the general favorable acceptance of *Acidophilus Bacillus Mulford* in trade channels as prepared and marketed, we prefer to continue without making any changes at present."

The labels received in February 1934 lacked a place for an entry of the date of manufacture, and claimed that at the time of sale each cubic centimeter contained "millions of *acidophilus* bacilli," in place of stating that there would be in each cubic centimeter at least 100 million of these organisms in a viable state. The cartons had the same defects. The trade package circular did not show the revisions indicated in the Council's report.

All of this material is printed in Spanish as well as in English, as the product is intended for sale in both South America and in this country.

On Feb. 28, 1934, the firm was informed of the defects of these labels, cartons and circulars and further informed that the material submitted with the firm's letter of Feb. 13, 1934, had not been revised in accordance with the material submitted on March 9, 1932, and hence did not meet the recommendations of the Council's report. To this the firm replied that if it "were to attempt to comply with the suggestions in detail, a continuance of the product on the market would prove impractical. However [it was added], we must hesitate in making it unavailable to the medical profession because of the favorable acceptance by physicians generally of *Acidophilus Bacillus Liquid-Mulford*, as now prepared and marketed."

The requirements which the firm held "impractical" are (1) improvement of the product so that it can be guaranteed to contain at least 200 million viable *B. acidophilus* organisms per cubic centimeter at the date of manufacture and 100 million per cubic centimeter at the date of expiration; (2) marking the dates of manufacture and expiration on the labels and cartons; and (3) omission of the use of the term "toxic conditions due to intestinal putrefaction." In the opinion of the Council's referee these requirements are not "impractical" and are both reasonable and possible of fulfilment.

In January and March 1934 a competent bacteriologist who has a special knowledge of *Bacillus acidophilus* examined *Acidophilus Bacillus Liquid-Mulford* as part of an investigation sponsored by the Council. His report on this preparation is as follows:

Samples purchased on the open market in January 1934 did not contain a date of manufacture. The product was guaranteed to contain "millions of viable *acidophilus* bacilli" per cc. at the date of sale. The carton of the sample purchased on January 25, 1934, bore the statement "Expiration date—Mar. 21, 1934."

The bacterial counts of *acidophilus* bacilli were as follows:

Medium	B. <i>Acidophilus</i> Counts, per Cc.	
	Jan. 25, 1934	March 21, 1934
Tomato juice agar (in air).....	41 million	17 million
Tomato juice agar (in 10% CO ₂)..	96 million	16 million
Casein digest agar (in air).....	39 million	20 million
Casein digest agar (in 10% CO ₂)..	91 million	5 million

This shows that at the date of the customer's purchase of this product in this country it was below the Council's standard by more than 100 million viable *B. acidophilus* organisms per cubic centimeter and that approximately two months later, at the expiration date marked on the carton of the sample examined, it was, at best, 80 million organisms per cubic centimeter under the minimal requirement of the Council. If, as stated, the preparation contained upward of 1,000 million viable *B. acidophilus* organisms at the time of manufacture, it is evident that great deterioration took place. The director of the firm's biologic laboratories admitted in his note of Jan. 29, 1934, that "a great deal of variation occurs in the keeping qualities of the individual lots regardless of time and temperature." The product is thus shown to be inferior to the Council's standards and subject to great and apparently uncontrollable deterioration.

Mulford *Acidophilus Bacillus* Blocks

The period of acceptance of this chocolate covered agar-*B. acidophilus* product expired with the close of 1933. In February 1934 the Council voted to reaccept the product until the end of 1934, provided the firm revised the carton, package enclosure and circular by removing the large initials "M. A. B." from the name, placed the date of manufacture and expiration date and a statement of the minimal number of viable *B. acidophilus* organisms per gram on the cartons or labels, submitted evidence that a six weeks expiration period was warranted, and revised the text of the package enclosure and circular. This report was sent to the firm Feb. 26, 1934. The firm acknowledged receipt of the report on March 5, 1934, writing: "We will write you further regarding this matter in about ninety days." Although more than ninety days has passed since then, and although the Council usually requires replies from firms within sixty days, no further communication has been received from Sharp & Dohme, Inc.

This product has recently been examined for the Council by a bacteriologist expert in work with *B. acidophilus*. His report is as follows:

Packages of *Mulford Bacillus Acidophilus* Blocks were purchased on the open market in February 1934. The labels did not contain any statement of the date of manufacture but guaranteed that at the time of sale each Block will contain "millions of viable *acidophilus* bacilli." The expiration date stamped on the carton of the sample was "March 18, 1934."

The bacterial (*B. acidophilus* per gram) counts were:

Medium	Feb. 20, 1934	March 19, 1934
Tomato juice agar (in air).....	59 million	25 million
Tomato juice agar (in 10% CO ₂)..	60 million	25 million
Casein digest agar (in air).....	58 million	21 million
Casein digest agar (in 10% CO ₂)..	51 million	19 million

The sample contained 1,400 bacterial and mold contaminants per gram of material.

It is obvious from this report that the product is considerably inferior to the Council's standards for *B. acidophilus* preparations (New and Nonofficial Remedies, 1934, p. 252).

This account of the Council's negotiations with the firm in connection with these two products reveals that Sharp & Dohme, Inc., has been dilatory and uncooperative and, after about two years of correspondence, flatly declines to meet the stipulations of the Council.

The Council voted that *Acidophilus Bacillus Liquid-Mulford* and *Mulford Acidophilus Bacillus* Blocks be omitted from New and Nonofficial Remedies because they are inferior to the

Council's standards and because Sharp & Dohme, Inc., has refused to comply with the Council's requirements relating to the improvement of the product, the labeling of the containers and the revision of the circulars, cartons, and labels.

The foregoing statement was sent to Sharp & Dohme, Inc. The firm replied:

"We have taken quite some time to consider the report which you intend to publish regarding these two products with special reference to the names and to the numbers of bacilli present at the time of sale and at the time of expiration. While we could further discuss the Council's position regarding the changes which they require we feel we would not be justified in prolonging the discussion, hence, we offer no further comments with reference to the position taken by the Council on these two products."

Although the firm did not reply to all the points at issue, it appeared quite evident that it did not intend to meet the requirements of the Council as to improvement of the product and necessary revisions of labels and advertising.

The Council reaffirmed its previous decision and authorized publication of the report.

Committee on Foods

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION, AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION. **RAYMOND HERTWIG, Secretary.**

HIGHLAND 100% PURE VERMONT MAPLE SAP SYRUP

Manufacturer.—Cary Maple Sugar Company, Inc., St. Johnsbury, Vt.

Description.—Pasteurized Vermont maple syrup prepared by evaporating and filtering maple sap.

Manufacture.—Maple sap is collected by farmers from sap spouts driven about one inch into maple trees. The sap flows into buckets, is delivered to evaporating houses, evaporated to standard weight, strained hot through felt into a tank where insoluble matter settles out, and is packed in drums, which are sent to the Cary company (which provides the drums), and the syrup is tested and graded for color, flavor and density. Only the best grade, based on color and flavor, is used for Highland brand. Syrup from the drums meeting requirements is emptied into large metal tanks, thoroughly mixed, pumped into glass lined vacuum cooking tanks, heated by steam, filtered under pressure through filter cloths and paper, returned to the glass lined cooking tanks, condensed to proper density (11 pounds to the gallon), and packed hot (82 C.) in hermetically sealed glass jugs and tins.

Analysis (submitted by manufacturer).—

		Moisture-free basis
Moisture	33.2%	
Ash	0.7%	1.0%
Soluble ash		0.6%
Insoluble ash		0.4%
Alkalinity of soluble ash (cc. N-10 acid to neutralize ash of 100 Gm. sample)	52 cc.	78 cc.
Alkalinity of insoluble ash (same)	76 cc.	114 cc.
Fat (ether extract)	0.0%	
Protein (N × 6.25)	0.0%	
Reducing sugars as invert sugar	4.2%	
Sucrose (by inversion)	60.0%	
Carbohydrates (by difference)	66.1%	
Lead number (Canadian)	4.4	
Lead number (Winton)	1.6	
Conductivity (25 Gm. solids)	138	
Malic acid value	0.70	
Direct polarization @ 20°C (26 Gm.)	56.8°V.	
Invert polarization @ 20°C (26 Gm.)	20.0°V.	

Calories.—2.6 per gram; 74 per ounce.

Claims of Manufacturer.—Complies with U. S. Department of Agriculture definition and standard.

DROMEDARY GRAPEFRUIT JUICE—SUGAR SYRUP ADDED

DROMEDARY ORANGE JUICE—SUGAR SYRUP ADDED

Manufacturer.—The Hills Brothers Company, New York.

Description.—Pasteurized Florida grapefruit juice and orange juice respectively with added sugar syrup, retaining in high degree the original vitamin content.

Manufacture.—Tree ripened fruit is used. The juice is removed from the cut fruit by burring, is strained to remove coarse pulp, is tested for acidity and sweetness and is admixed with sufficient sugar syrup to produce the desired flavor, is pasteurized, is automatically canned, and is processed below 100 C. for about fifteen minutes.

Analysis (submitted by manufacturer).—

Grapefruit Juice:	per cent
Moisture	83.7
Total solids	16.3
Ash	0.5
Fat (ether extract)	0.4
Protein (N × 6.25)	0.7
Reducing sugars as invert sugar	8.9
Sucrose	4.4
Crude fiber	0.3
Carbohydrates other than crude fiber (by difference) ..	13.4
Titrate acidity as citric acid	0.8-1.0

Orange Juice:	per cent
Moisture	84.0
Total solids	16.0
Ash	0.7
Fat (ether extract)	0.3
Protein (N × 6.25)	0.8
Reducing sugars as invert sugar	5.7
Sucrose	6.7
Crude fiber	0.4
Carbohydrates other than crude fiber (by difference) ..	13.0
Titrate acidity as citric acid	0.8-1.0

Calories.—0.6 per gram; 17 per ounce.

Vitamins.—Biologic assay shows retention in large measure of the original vitamin C content.

Claims of Manufacturer.—Retain practically all the nutritional values of the natural fruit juices and are intended for all the dietary and table uses of grapefruit and orange juices.

BORCHERDT'S MALT EXTRACT (PLAIN)

CONTAINS 10 PER CENT GLYCERIN

Manufacturer.—Borchardt Malt Extract Company, Chicago.

Description.—Concentrated diastatically active malt extract (U. S. P.) with 10 per cent glycerin added.

Manufacture.—An infusion of crushed high diastatic barley malt is maintained at a fixed temperature for a definite time, filtered, and the filtrate concentrated in vacuum to the desired density. Ten per cent by weight of glycerin is added and the mixture packed in bottles.

Analysis (submitted by manufacturer).—

	per cent
Moisture	22.3
Ash	1.1
Protein (N × 6.25)	4.4
Reducing sugars as maltose	52.5
Dextrins (by difference)	9.
Titrate acidity as lactic acid	0.7
Glycerin	10.
Calcium (Ca)	0.02
Iron (Fe)	0.0005
Magnesium (Mg)	0.08
Phosphorus (P)	0.25
Potassium (K)	0.25
Sodium (Na)	0.09

Diastatic value (U. S. P. method).

One Gm. converts from 5 to 7 Gm. of starch into maltose and dextrins in thirty minutes at 40 to 42 C.

Calories.—3.1 per gram; 88 per ounce.

Vitamins.—One ounce contains between 56 and 60 units of vitamins B and G (Sherman and Pappenheimer).

Claims of Manufacturer.—Easily assimilable. A valuable carbohydrate supplement to milk.

SATURDAY, DECEMBER 22, 1934

DINITROPHENOL IN OBESITY

Since the clinical report on the use of alpha-dinitrophenol in obesity appeared in *THE JOURNAL*,¹ interest in this product and its actions has been widespread. Unimpeded by marketing restrictions, dinitrophenol has been sold and used indiscriminately with the inevitable serious toxic effects. Reports of its toxicity have, in fact, persuaded many physicians to suspend use and final judgment until the results of further studies should be known. That this policy has not been followed by all is amply demonstrated in the figures cited by Tainter, Cutting and Stockton² in their recent critical review of the subject. Thus they state that during the previous year the Stanford Clinic supplied physicians, or patients on physicians' prescriptions, with more than 1,200,000 capsules of dinitrophenol of 0.1 Gm. each. Since the usual daily dose is about three such capsules and the average duration of treatment about three months, this corresponds to 4,500 patients treated with the drug in a year. They estimate that probably at least 100,000 persons have been treated with the drug in this country alone. This number appears sufficient for preliminary summarization and analysis.

Basically there are two paramount features to consider. There is no doubt that dinitrophenol can increase the tissue metabolism, probably by direct action on the cells and without producing the side actions that accompany metabolic stimulation by thyroid. The second important fact is that the margin between therapeutically tolerated doses and definitely toxic ones is often narrow. All studies of this drug must of necessity be grouped around these considerations.

At present the principal therapeutic interest of dinitrophenol lies in the loss of weight occurring in obese individuals as a result of the increased metabolism

produced by this drug. When taken in adequate dosage, the increased metabolic activity burns extra fat and carbohydrate without appreciably affecting the protein as indicated by nitrogen excretion. With these facts there appears to be no serious quarrel, although opinions as to the clinical efficacy vary.

Tainter and his co-workers have considered the toxic effects from the standpoint of fatalities and from the reported lesions of the skin, liver, kidneys, circulation, blood and gastro-intestinal tract. They cite three fatal cases resulting from the therapeutic ingestion of dinitrophenol. In one of these there was a definite question as to the true cause of death, since the clinical history and the course were at variance with the known actions of the drug. In neither of the other two cases was the use of the drug confined to the usual therapeutic doses.

In a group of 113 obese persons treated by dinitrophenol, skin rashes were observed in about 7 per cent. Since these skin rashes may be unpleasant or alarming in some instances, they constitute the main disadvantage, Tainter believes, in the therapeutic use of dinitrophenol. About half of the patients who have had one skin reaction are able, however, to resume the medication later without any further difficulty. With regard to liver damage it appears that ordinarily there is no demonstrable evidence of injury of this organ from the drug. In fatal cases destructive changes may occur in the liver as well as in the other viscera, but since those reported were accompanied by high fever the latter could itself account for the morphologic changes observed in the liver cells. The possibility must be left open, however, that in occasional patients an idiosyncrasy may exist which might mediate damage to the liver. Possible toxic effects on the kidney seem to be even more remote.

In considering the circulatory system Tainter and his co-authors say: "One of the most striking features of the metabolic stimulation of dinitrophenol is a lack of significant changes in the blood pressure or pulse rate, unless therapeutic doses are exceeded. That is, the metabolism may be increased by as much as 50 per cent without demonstrable changes in circulatory activity.

. . . Patients who have hypertension can be medicated with dinitrophenol like other patients. As they lose weight the hypertension is usually improved." It is perhaps malignant neutropenia occurring during dinitrophenol medication³ that has aroused the greatest professional alarm. Although Tainter and his co-workers have seen no cases of agranulocytosis and have observed no other abnormalities of the blood affecting the hemoglobin or the fragility of the red cells, they feel that the possibility of agranulocytosis must be borne in mind pending further observations.

2. Tainter, M. L.; Cutting, W. C., and Stockton, A. B.: Use of Dinitrophenol in Nutritional Disorders, *Am. J. Pub. Health* **24**:1045 (Oct.) 1934.

3. Hoffman, A. M.; Butt, E. M., and Hickey, N. G.: Neutropenia Following Amidopyrine: Preliminary Report, *J. A. M. A.* **102**:1213 (April 14) 1934. Bohn, S. S.: Agranulocytic Angina Following Ingestion of Dinitrophenol, *ibid.* **103**:249 (July 28) 1934. Silver, Solomon: A New Danger in Dinitrophenol Therapy, *ibid.* **103**:1058 (Oct. 6) 1934.

There seems to be agreement at present that dinitrophenol is a drug of potential dangers when used indiscriminately. Its sale should be restricted to that ordered by the physician's prescription and its use by medical men should be carefully supervised. Probably it should be employed only when reduction of obesity is important and when ordinary dietary methods have failed.

THE NATURE AND FOOD VALUE OF BEER

Since the return of beer to a place of importance in the diets of many persons in this country, the medical profession should be well informed concerning the contents and physiologic effects of this drink.

Beer is essentially a fermented beverage prepared from an infusion of hops and malted barley, with or without unmalted cereal grains other than barley. A brief description of the essential steps of manufacture has been recently given by Mathis and Bailey.¹ The first step is the preparation of malt, for which purpose barley is usually chosen. The process consists in steeping the barley in water to facilitate germination, which is followed by drying. The development of enzymes, primarily diastase and protease, is the primary object of malting. The second essential step is the preparation of "mash." The diastase of malt is sufficient to convert more than the starch in the malt itself into fermentable sugar; hence the practice of mashing a mixture of malt with raw (unmalted) cereals. The malt and raw grains are crushed and mixed with water, and the "mash" is allowed to stand at suitable and controlled temperatures. During this process the cereal starches are converted into fermentable sugars and the proteins are in part transformed into soluble forms such as amides, peptones and albumoses. The liquid is drawn off, the mash washed and the washing added to the liquid. This product constitutes the beer wort. After the wort has been boiled, hops are added and the boiling is continued. After cooking and sedimentation, the wort is drawn off or filtered and is ready for fermentation. The final process of fermentation is produced by the addition of selected cultures of yeast and may be carried out in various ways and at different speeds. Naturally this is only a general description of the process, since each constituent and each step is part and parcel of the distinctive nature of different types and brands of beer.

One of the final products of especial importance is the alcoholic content, which has been the subject of numerous reports.² Thus soon after the 3.2 per cent beer legislation an analysis of fifty-two brands of beer was made by the New Hampshire State Board of Health and reported in *THE JOURNAL*.^{2b} The average

alcoholic strength of these samples was found to be 3.68 per cent by volume. The lowest was 3.2 and the highest was 4.1 per cent. Similarly Mathis and Bailey report the analysis of the alcohol percentage by volume of a number of beers before and after repeal of the eighteenth amendment. Of thirty-seven domestic light beers before repeal, the average alcohol by volume was 3.7 per cent, the maximum 4.03 and the minimum 3.01. Of ten light beers (many of the brands included in the earlier analysis) analyzed after repeal, the average alcohol by volume was 4.64, the maximum 5.23 and the minimum 4.02.

The food value of beer as measured by calories is not wholly dependent on the alcoholic content. For example, Lusk³ states that "a liter of German beer contains from 3 to 4 per cent of alcohol and from 5 to 6 per cent extractives. It yields 450 calories to the body, only half being derived from alcohol, the rest from dextrin and protein-like extractives. Here is a food material whose 'fattening' properties may be very highly considered." Christie⁴ has considered the same subject in relation to the nutritive value of other fluids containing alcohol. While the number of calories per ounce of the malt liquor is for the most part lower than that of an equal quantity of wines, liqueurs and spirits, the former are usually taken in much larger quantities than the latter and hence the total calory intake is generally more. Christie concludes, therefore, that light beers are ideal for the undernourished, and if the calories of beer are added to those of the usual diet there would seem to be no doubt of the practical value of his statement.

PROBLEMS OF LATENT INFECTION

In the English language the word infection may mean not only the infectious agent itself but also its entrance into the body and all the consequences of such entrance. Latent infection, generally speaking, means the residence in the body of a specific infectious agent without any manifest symptoms. The symptomless incubation period, which in certain diseases, notably measles and smallpox, is fairly definite in length, is a period of latency in infection. After complete recovery from an infectious disease the infectious agent may survive in the patient for a variable time, sometimes for years, without causing any obvious disturbances. Here the infection outlives the disease. This form of latency in infection occurs in typhoid, cholera, epidemic meningitis, diphtheria, scarlet fever and other diseases. In malaria, recurrent fever, undulant fever and septicemic infections occur symptomless intervals or periods of latency the nature of which presents many problems. There are also infections that may remain latent throughout their entire course, which may end in the

complete sterilization of the patient. This form of latent infection has been studied experimentally in dengue and typhus fever. Without any manifest symptoms the blood becomes infectious and then sterile again at the same time as immunity to reinfection is established. The most common example of this category of latent infection is seen in the diphtheria carrier without diphtheria. Undoubtedly the same form of latency occurs in scarlet fever. In these as well as in other latent infections the body is subjected to the action of antigenic substances, to which it may respond by the production of new antibodies. This is illustrated clearly by the development of specific antitoxin in the blood in latent diphtheria or scarlet fever carriers. And in the latent infection of the incubation period of smallpox and vaccination the body responds almost immediately by increased sensitiveness or allergy to the variolous or vaccinia virus. Finally are mentioned the deposition in the body of various infectious agents that remain localized and latent for long periods. Here belong small tuberculous foci, latent tetanus, latent rabies and bartonella infection in rats. The conditions under which latent infections of this group become manifest are not understood any more than the conditions that lead to latency in the first place, but it is evident that, in all forms of latency of infection, processes of adaptation between parasite and host are at work.

In the acute infectious diseases, latent infection has an important epidemiologic rôle for two reasons: first, it increases greatly the number and mobility of the sources of infection, and, second, it favors the development of resistance to infection by its immunizing influence. The diseases in which latency of infection has been studied most so far seem to be yellow fever, typhus fever, diphtheria, scarlet fever, epidemic poliomyelitis and epidemic meningitis. At this time only diphtheria may be considered with some detail. It is well known that not all persons exposed to diphtheria become ill. Is that because diphtheria is not easily communicable? Not at all. The reason is that there are two kinds of susceptibility to diphtheria, susceptibility to manifest infection and susceptibility to latent infection. If diphtheria was not easily communicable there would not be so many carriers of diphtheria bacilli. It has been estimated that in large centers of population every one becomes a carrier once every three years. In the meantime, carriership or latent infection results in latent immunization against the toxin.

A question that agitates investigators in this field now is whether the antitoxin found in the blood of so many carriers is the result of latent immunization or the product of a normal "serologic ripening" independent of specific antigenic stimulation. The weight of evidence is altogether in favor of latent immunization. It is claimed that certain so-called normal or natural immune bodies develop under conditions that exclude the influence of antigenic stimuli, but it is not possible to exclude definitively the entrance into the body by

absorption from the digestive tract, the respiratory tract, the skin, or by latent infections, of antigenic substances to account for all the antisubstances found in the blood under so-called normal conditions. It has also been asserted that diphtheria antitoxin is present in the blood in people in Greenland and in Africa, where it is supposed that there is no clinical diphtheria and no diphtheria carriers, but it is pointed out clearly by Dudley¹ that the presence of diphtheria bacilli among these people cannot be excluded and that the complete distribution of antitoxic immunity in time and space cannot be explained adequately by the theory of "serologic ripening." Latent infection with the resulting immunization is an attractive field for scientific investigation.

Current Comment

SERUM AND LYMPH

The individual cells of the body exist essentially in a fluid medium. Food must be presented in solution, and waste products of metabolism must be removed in like manner. The fluid exchange in the organism therefore assumes a fundamental importance. The blood volume must be maintained, yet fluid must pass through the blood vessel walls to reach the tissue cells. The serum proteins because of their failure to diffuse readily maintain the balance of power in holding water in the vessels through their small but definite osmotic pressure. Field, Leigh, Heim and Drinker¹ have recently described the relationship between the proteins and osmotic pressure of serum and of lymph from various parts of the body. The total protein content of lymph is less than that of the serum. It appears that albumin constitutes a greater proportion of the total protein in cervical, thoracic duct and leg lymph than it does in the serum. Only in lymph from the liver was this relation reversed. When the osmotic pressure of these body fluids was related to the quantity of contained protein it was observed that, except in the case of the lymph from the liver, all the samples showed essentially the same value as did the serum. The authors believe that the composition of the lymph collected from the legs of the experimental animals during walking represents fairly well that of the capillary filtrate. It would appear that temporarily, under these conditions of muscular exercise, the difference between the colloidal osmotic pressure of the serum and that of the lymph is less than the capillary pressure, with the result that nutrient fluid more readily escapes into the extravascular spaces and reabsorption is at a minimum. These studies emphasize again the delicate fluid balance normally maintained in the organism and the highly responsive mechanism on which it depends.

A STATEMENT BY PRESIDENT ROOSEVELT ON RESPONSIBILITY FOR CARE OF THE SICK

A significant statement made by the President of the United States appears in a letter, which it was announced on December 11 he had sent to David H. Pyle, president of the United Hospital Fund in New York City. The letter was an endorsement by the President of a campaign for \$500,000 toward the free work of fifty-six voluntary hospitals.

In his opening paragraph the President said:

"While the Federal Government has necessarily stepped in to aid the states and localities in providing relief for the needy unemployed in their homes, it is impossible to make government funds available to the hospitals for the care of the sick who lack funds to pay. Yet such patients are among the most needy of all the victims of unemployment. *I have repeatedly stated my feeling that the care of the sick is a local responsibility.* All over the land communities are rising manfully to fulfil this obligation."

The italics are ours.

SOCIALIZED MEDICINE JEOPARDIZES OFFICE BUILDINGS

In a periodical called *Skyscraper Management*, Mr. Frank M. Whiston, manager of the Pittsfield Building in Chicago, presents a few considerations relative to the manner in which changes in the nature of the practice of medicine may affect the owners of large buildings:

"What owner or manager of a building having medical or dental occupancy has not had, within the past year or two, many of his tenants walk in and say that they cannot continue their office and ask that their lease be terminated, their rent be reduced to a ridiculous figure, or that an indefinite extension of credit be granted?"

"The medical profession has suffered a series of adversities which it was wholly unprepared to withstand. Every business and profession has experienced the hardships of depression—there is nothing unusual about that—but for the physicians and dentists, the effects have been cumulative and augmented by sinister developments that strike at the foundations upon which the structure of professional practice has been established."

"Corporate medicine often has political affiliations since it depends, in some measure, upon permissive legislation. And, close behind the menace of corporate medicine is, perhaps, the greater menace of state medicine.

"What such developments mean to the medical profession is all too obvious. What they mean to property that has been erected to meet the requirements of the medical profession is equally apparent.

"Granting all these things are true, the factors we, as owners and managers, are interested in primarily are those over which our tenants have little or no control because of their comparatively small influence from a numerical standpoint."

"Corporate medicine might become a politically controlled machine within city limits. It presents a grave hazard to the professional man, to us as building managers and to us as individuals. Rumbblings are heard, strong forces are at work to project into the picture a corporate medical ordinance, probably state, and possibly federal legislation, to make it obligatory upon employees to be examined and then to use the particular physician designated to them for a treatment of their ailments. The imagination does not have to run wild to visualize the possibilities in such a step, where circles are drawn in neighborhoods and you'll take the physician within your circle and like it!—it is being done in some parts of Europe today."

"Unless the control of health insurance, state medicine or whatever change in the method of payment is not left in the hands of the organized profession, it will mean the disintegration of medical buildings, so here we are and now let us see what must be done."

Association News

THE ATLANTIC CITY SESSION Special Exhibit on Diabetes

The Committee on Scientific Exhibit of the Board of Trustees has announced that arrangements are in progress for a special exhibit on diabetes in the Scientific Exhibit at the Atlantic City session. The following individuals have accepted membership on the diabetes exhibit committee:

E. P. Joslin, chairman, Boston.
F. G. Banting, co-chairman, Toronto.
C. H. Best, Toronto.
H. F. Root, Boston.
R. M. Wilder, Rochester, Minn.
R. T. Woodyatt, Chicago.

A corps of competent demonstrators will assist this committee in presenting the subject in all its phases.

Special Exhibit on Vaccines and Serums

The Committee on Scientific Exhibit of the Board of Trustees has also authorized a special exhibit at the Atlantic City session on vaccines and serums. The committee in charge is as follows:

R. C. Williams, chairman, Washington, D. C.
J. P. Leake, Washington, D. C.
W. G. Workman, Washington, D. C.

The exhibit will include the clinical factors concerned in the use of vaccines and serums and especially recent developments in connection with these products.

Special Exhibit on Nutrition

The special exhibit on nutrition will be conducted for the second year at the Atlantic City session under the auspices of a special exhibit committee as follows:

Reginald Fitz, chairman, Boston.
W. C. Alvarez, Rochester, Minn.
L. H. Newburgh, Ann Arbor, Mich.

The cooperation of various experts in nutrition will be utilized for the presentation and demonstration of the exhibit.

APPLICATIONS FOR GRANTS FOR RESEARCH

The Committee on Scientific Research of the American Medical Association invites applications for grants in aid of research on problems bearing on the clinical aspects of medicine and surgery. Inquiries may be addressed to the committee at 535 North Dearborn Street, Chicago.

MEDICAL BROADCASTS

Columbia Broadcasting System

The American Medical Association broadcasts on a western network of the Columbia Broadcasting System each Thursday afternoon on the Educational Forum from 4:30 to 4:45, central standard time. The next three broadcasts will be delivered by Dr. W. W. Bauer. The titles will be as follows:

December 27. Budgeting for Health.
January 3. Housing and Health.
January 10. Diphtheria Must Go.

National Broadcasting Company

The American Medical Association broadcasts under the title "Your Health" on a Blue network of the National Broadcasting Company each Tuesday afternoon from 4 to 4:15, central standard time. The next broadcast will be delivered by Dr. Thomas S. Cullen. The title will be as follows:

December 25. Holiday; no broadcast.
January 1. Holiday; no broadcast.
January 8. Research in Medicine.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

ALABAMA

County Health Department Discontinued.—The Geneva County Health Department has been discontinued in accordance with a decision of the board of commissioners. Dr. Lucius S. Nichols was the county health officer.

Personal.—Dr. James S. Hough, Livingston, health officer of Sumter County, has been made district medical superintendent in charge of eleven counties, effective December 1.—Dr. Henry T. Donovan, Marion, has been appointed health officer of Shelby County, succeeding Dr. John M. Kimmey, Columbiana.—L. V. Phelps, formerly statistician with the New York State Health Department, has been appointed in charge of the bureau of vital statistics of the Alabama State Health Department, succeeding Mr. W. T. Fales, who resigned after ten years' service to accept a similar position with the Baltimore Health Department. Mr. Phelps' appointment was effective December 1. He is a graduate of Boston University and pursued graduate studies in the School of Public Health of the Massachusetts Institute of Technology, Cambridge.—Dr. Edward A. Thorne, Fairfield, was recently appointed health officer of Jackson County, succeeding Dr. Lucian Newman, who resigned to enter private practice in Dadeville.

ARKANSAS

District Meetings.—Dr. Ira W. Ellis, Monette, was elected president of the First Councilor District Medical Society at its meeting in Jonesboro, recently; Dr. Robert H. Willett, Jonesboro, is vice president, and Dr. Ralph M. Sloan, Jonesboro, secretary. Speakers were the following physicians:

Horace R. McCarroll, Walnut Ridge, Obstetrics at the Bedside.
Richard C. Bunting, Memphis, The Variability in Symptoms and Treatment of Encephalitis.
Lorenzo D. Massey, Osceola, The Dysenteries with Reference to Sodium Thiocyanate in Their Treatment in 1933 and 1934.
George V. Lewis, Little Rock, Infections of the Hand.
Silas C. Fulmer, Little Rock, Symptoms and Diagnosis of Heart Disease.
John E. McGuire, Piggott, Diphtheria.

At a meeting of the Third District Medical Society in Stuttgart, November 27, Drs. James S. Speed, Memphis, Tenn., discussed "Early Diagnosis of Osteomyelitis," and Joseph F. John, Eureka Springs, "Home Treatment of Peptic Ulcer." Dr. Aris W. Cox, Helena, spoke on "Foreign Bodies in the Auditory Canal" at the evening session, and Dr. Jesse D. Riley, State Sanatorium, showed lantern slides demonstrating studies of tuberculosis.

CALIFORNIA

University News.—The Alumni Association of the College of Medical Evangelists, Los Angeles, held a graduate assembly, December 9; Dr. Bernard Myers, president, clinical section, Royal College of Physicians of London, participated in the program; his subject was "Essential Thrombocytopenic Purpura Haemorrhagica." Dr. Myers addressed the faculty and students of the University of California Medical School, December 10, on the same subject.

Personal.—Dr. Anne L. Brady has been appointed city health officer of Ross to succeed Dr. George H. Willcutt.—Robert A. Millikan, Ph.D., Pasadena, was awarded the Cardinal Newman medal, November 7, for achievement in the field of physical science. Dr. Millikan is the first scientist to receive the award, which is presented annually by the Newman Foundation of the University of Illinois to "some person who has rendered some contribution to the enrichment of human life."—Dr. Paul M. Hamilton, Alhambra, has been appointed in charge of the department of contagious diseases at the Los Angeles General Hospital.—Dr. Jacob C. Geiger, health officer of San Francisco, has been elected president of the San Francisco County Medical Society.

CONNECTICUT

Personal.—Dr. Clarence E. Simonds has been appointed health officer of Windham, succeeding the late Dr. Frederick E. Wilcox.—Dr. David Leonard Lieberman has been appointed health officer of Chester, succeeding Dr. William J. Tate, Deep River.

Towns Without Physicians.—Forty-five towns in Connecticut have no physician, according to a recent compilation dealing with the location of physicians in the state. About 70 per cent of the physicians are located in Hartford, New Haven and Fairfield counties. The total number of physicians in the state is 2,027. According to the *Connecticut Health Bulletin*, the four largest cities have 48.5 per cent of the total physicians, and all other cities with more than 5,000 population have 41.6. The four largest cities claim 995 of the total, while the population group 25,000 to 49,999 claims the next largest group of physicians, with 391 of the 2,027. There are 847 physicians in cities of from 5,000 to 99,999 population. This accounts for all but 185 of the physicians, who are divided among the remaining 113 towns of the state.

DELAWARE

Society News.—Dr. John E. James, Philadelphia, addressed the New Castle County Medical Society, November 20, on "Practical Obstetrics."

Health at Wilmington.—Telegraphic reports to the U. S. Department of Commerce from eighty-six cities with a total population of 37 million, for the week ended December 8, indicate that the highest mortality rate (23.5) appears for Wilmington, and for the group of cities as a whole, 11.7. The mortality rate for Wilmington for the corresponding period last year was 14.7, and for the group of cities, 12. The annual rate for eighty-six cities for the forty-nine weeks of 1934 was 11.3, as compared with a rate of 10.9 for the corresponding period of the previous year. Caution should be used in the interpretation of weekly figures, as they fluctuate widely. The fact that some cities are hospital centers for large areas outside the city limits or that they have a large Negro population may tend to increase the death rate.

DISTRICT OF COLUMBIA

Personal.—Brig. Gen. Jefferson R. Kean, medical corps, U. S. Army, retired, has been appointed a member of the commission recently authorized by Congress to consider and formulate plans for the construction on the banks of the Mississippi near St. Louis of a permanent memorial to the men who made possible the territorial expansion of the United States.

Society News.—Dr. Pol N. Coryllos, New York, addressed the Medical Society of the District of Columbia, December 12, on surgical treatment of pulmonary tuberculosis.—Speakers before the Medical Arts Society in Washington in November were Drs. Claude Moore on "Recent Developments in the Diagnosis of Gallbladder Disease" and John M. Baber, "Congenital Syphilis with Enlarged Spleen and Liver."

GEORGIA

Personal.—Dr. Horace G. Huey, Homerville, has been named chairman of the Georgia State Board of Medical Examiners for the coming year.—An oil portrait of Dr. Floyd W. McRae Sr. was presented to the library of the Fulton County Medical Society as a memorial to him. The portrait was painted by a member of the society.

Pediatric Meeting.—The second annual meeting of the Georgia Pediatric Society was held in Atlanta, December 13. The program included the following:

Dr. Gilbert J. Levy, Memphis, Treatment of Meningitis.
Dr. Robert A. Strong, New Orleans, Erythroblastic Anemia.
Dr. Wilbur C. Davison, Durham, N. C., Pediatric Therapeutics.
Dr. Albert Graeme Mitchell, Cincinnati, Studies of Nonspecific Effects on the Tuberculin Reaction.
Dr. Edwards A. Park, Baltimore, Scurvy Without Clinical Manifestations.

At the evening session the Fulton County Pediatric Society acted as host to the guest speakers and members of the Georgia Pediatric and Fulton County Medical societies.

New Buildings at Warm Springs.—The dedication of two new buildings at Georgia Warm Springs Foundation, Warm Springs, took place Thanksgiving Day as part of the general celebration participated in by President Roosevelt, the patients and the staff. The buildings represent part of the expenditure of more than \$1,000,000, which was subscribed at the charity balls held throughout the country in honor of President Roosevelt's birthday. According to the *New York Times*, the buildings are not pretentious, since most of the money was invested in an endowment or given to other institutions to further research into means to prevent infantile paralysis. One of the buildings contains more than thirty rooms for patients, parlor and recreation room. All the furnishings and decorations are devoid of hospital atmosphere.

MASSACHUSETTS

Memorial Service for Dr. Folin.—Faculty members and students of Harvard Medical School paid tribute in a memorial service, November 23, to the late Dr. Otto K. O. Folin, Kuhn professor of biological chemistry at the school since 1907. Dr. Folin died October 25 in his sixty-seventh year. The meeting was addressed by Dr. Walter B. Cannon, Higinson professor of physiology; Dr. Cyrus H. Fiske, associate professor of biological chemistry, and Dr. Henry A. Christian, Hersey professor of the theory and practice of physic. At the close of the exercises Dr. Cannon, acting for the faculty, presented a portrait of Dr. Folin to the university. Originally this portrait was to have been given in Dr. Folin's presence at a dinner celebrating his long service. In 1918 Dr. Folin was awarded an honorary degree of doctor of medicine by the University of Lund, Sweden. He graduated from the University of Minnesota in 1892 and received degrees of doctor of philosophy and doctor of science from the University of Chicago. Since 1926 he had been a member and chairman of the division of biochemistry of the National Board of Medical Examiners as well as a member of its examination committee.

Society News.—At a meeting of the New England Physical Therapy Society in Boston, October 24, Dr. John G. Kuhns, Boston, discussed the mechanics of the spine and thorax. —Dr. Channing C. Simmons, Boston, presented cases of tumors of bone in a discussion before the New England Roentgen Ray Society, October 26. —Drs. Philemon E. Truesdale and Joseph H. Marks, Fall River, discussed "Diaphragmatic Hernia and Associated Conditions" before the New England Roentgen Ray Society, November 16. —At a meeting of the Harvard Medical Society in Boston, November 13, Dr. George Pinness, Los Angeles, discussed "Gastro-Intestinal Allergy and Its Diagnosis," and Dr. Francis M. Rackemann, Boston, "New Concepts in Allergy, with Especial Reference to Eczema." —Dr. Foster Kennedy, New York, addressed the William Harvey Society in Boston, November 9, on "The Biopsychic Approach to Diseases of the Mind, Its Dependence on Neurology and General Medicine." —Dr. Hiram Houston Merritt Jr., Boston, discussed "Neurology and Neurosyphilis" before the Fall River Medical Society, November 21. —Speakers before the Massachusetts Society of Examining Physicians, November 14, included Dr. Louis Schwartz of the U. S. Public Health Service, New York, on "Diagnosis of Industrial and Nonindustrial Skin Diseases." —The New England Hospital Association will hold its thirteenth annual meeting at the Bradford Hotel, Boston, February 7-9.

MICHIGAN

Dr. Novy Retires as Dean.—Dr. Frederick G. Novy, dean of the University of Michigan School of Medicine, Ann Arbor, since September 1933, announced his retirement, effective at the close of the current semester. Dr. Novy's resignation ends forty-eight years' association with the institution. He graduated from the University of Michigan School of Medicine in 1891. He was appointed assistant in organic chemistry in 1886 and has been professor of bacteriology and director of the Hygienic Laboratory since 1902. He was a member of the U. S. Commission to investigate plague in 1901 and a member of the state board of health, 1897-1899. He has contributed much to the literature of bacteriology and related subjects.

Society News.—At a meeting of the Ionia-Montcalm County Medical Society in Belding, October 9, speakers were Drs. Arthur R. Woodburne and William J. Butler, Grand Rapids, on treatment of syphilis and management of prostatic obstruction, respectively. —Dr. Frederick C. Kidner, Detroit, discussed modern conceptions of bone tuberculosis and infantile paralysis before the Saginaw County Medical Society, Saginaw, October 30. —Dr. Earl I. Carr, Lansing, discussed "Achievements in Cancer Control" before the Wayne County Medical Society in Detroit, December 3. —Dr. Raphael Isaacs, Ann Arbor, addressed the Washtenaw County Medical Society, November 13, on diagnosis and treatment of some of the diseases of the blood-forming organs. Malcolm H. Soule, LL.D., Ann Arbor, addressed the society, October 9, on "Leprosy in the Philippine Islands." —Dr. Carl E. Badgley, Ann Arbor, addressed the Kalamazoo Academy of Medicine, November 20, on "The Importance of the Lumbosacral Joint in Low Back Disturbance." —Dr. Jacob P. Greenhill, Chicago, spoke before the Ingham County Medical Society in Lansing, November 30, on "Recent Advances in Obstetrics and Gynecology." —Dr. Daniel Budson, Detroit, was elected president of the University of Michigan Pediatric and Infectious Disease Society at its recent meeting, and Dr. David Murray Cowie, Ann Arbor, secretary. The next annual session will be held at

Ann Arbor, Nov. 22-23, 1935. —Dr. Clifford P. Clark, Flint, addressed a meeting of the Genesee County Bar Association, November 23, on medicine and law.

MISSISSIPPI

Society News.—At a meeting of the Delta Medical Society, recently, speakers included Drs. Oscar E. Ringold, Cleveland, on "Intravenous Magnesium Sulphate in Treatment of Spider Bites," and Chauncey W. Dowden, Louisville, "Differential Diagnosis and Treatment of Hyperthyroidism." —A symposium on backache was presented before the Central Medical Society, recently, by Drs. James W. Lipscomb Jr., Columbus, and Thomas H. Blake, Jackson. Other speakers were Dr. Henry Boswell, Sanatorium, on the field conservation service for tuberculosis; Lew Wallace, Laurel, relationships between druggists and doctors, and Dr. George E. Riley, Jackson, diagnosis and treatment of malaria. —The Clarksdale and Six Counties Medical Society was addressed at Clarksdale, November 14, by Drs. James D. Biles, Jr., Sumner, on "Our Greatest Curse: Purgation"; Felix J. Underwood, Jackson, "Trends in Medicine and Public Health," and Joseph A. Crisler Jr., Memphis, "Atypical and Borderline Hyperthyroidism." —Dr. Laurance J. Clark read a paper on tuberculosis before the Issaquena-Sharkey-Warren Counties Medical Society, Vicksburg, November 13, and Dr. Walter E. Johnston presented a case of mesenteric thrombosis.

NEW YORK

New Milk Code in Effect January 1.—Following a survey to determine whether milk producers who have made reasonable efforts to qualify for the sale of the new high grade of raw milk have had sufficient time to rid their herds of infectious abortion, the state department of health announces that the new regulation will go into effect January 1. The new grade, known as Special A Raw, was established by an amendment to the Sanitary Code in December 1933. The amendment provided that after July 1, 1934, the new grade was to be from herds free from mastitis and infectious abortion, and further that after January 1 in cities and incorporated villages with populations of 15,000 or more no raw milk other than "Certified" and the new grade could be sold. Later the date for the first requirement was deferred to January 1 on representations from the producers that the time was too short. Because of doubt still expressed that the time was adequate, the department made its survey. It was found that all but a few of the raw milk dealers who wished to qualify for the sale of the new grade would be able to meet the requirements by January 1, that many had decided not to undertake production of Special A Raw and had begun pasteurization, and that in a few cities groups of raw milk dealers had made no effort to meet the requirements but had apparently assumed that they would not be enforced. In view of these facts, the date remains as set.

New York City

Standard Formulary Adopted in City Hospitals.—A hospital formulary containing about 1,200 preparations has been adopted by the hospital department for all city institutions. It is asserted that this move will facilitate the work of physicians and pharmacists and will be an economy for the city.

Gifts to New York University.—Among gifts received for medical purposes during the past year by New York University are the following:

Carnegie Corporation of New York, \$43,750 for support of the medical college.

Anonymous gift of \$10,000 for support of the neurologic research laboratory.

Mead Johnson and Company, \$6,000 for vitamin research.

International Cancer Research Foundation, \$4,500 for research in cancer.

Eli Lilly and Company, the New York Foundation and an anonymous donor, \$3,756 for research in anterior poliomyelitis under direction of Dr. William H. Park.

Dr. William H. Park, \$3,000 to support the department of preventive medicine.

Lederle Laboratories, \$2,500 for experimental work in liver extract.

Josiah Macy Jr. Foundation, \$2,500 for the neurologic research laboratory fund for migraine.

Dr. Norris Awarded Academy Medal.—Dr. Charles Norris, chief medical examiner of New York City, was awarded the gold medal of the New York Academy of Medicine at its annual meeting, December 6, for distinguished service in medicine. In the citation it was affirmed that Dr. Norris's services have been of inestimable value to the city and to the medical profession and that he has been "a great factor in cleaning up the very undesirable conditions that formerly existed in the coroner's office." The academy's medal was first awarded in 1930 to Dr. Carl Koller and again in 1931 to Dr. David Marine. It was established by Dr. Samuel

McCullagh. At this meeting of the academy Dr. Eugene H. Pool was elected president for two years.

Society News.—The Baltimore Medical Club of New York held its tenth annual dinner at the Fifth Avenue Hotel, December 14. Dr. Robert P. Bay, Baltimore, read a paper on "Acute Torsion of the Omentum," and Dr. Harlow Brooks gave a travel talk on Mexico.—Dr. Morris K. Smith addressed the New York Surgical Society, December 12, on "Surgical Treatment of Toxic Goiter."—Drs. William V. P. Garretson and Robert A. Cooke addressed the Medical Association of the Greater City of New York, on "Allergy—A Neuro-Endocrine Interpretation" and "Importance of Allergy to the General Practitioner," respectively.—Drs. William Darrach, Arthur Krida and John J. Moorhead presented a symposium on "Surgical Management of Automobile Accident Injuries" before the Medical Society of the County of New York, December 21.—Drs. Russell Burton-Opitz and Alexander L. Louria, Brooklyn, addressed the International Association of Industrial Surgeons, November 30, on "Interpretation of the Electrocardiogram" and "Role of the Normal and Pathologic Heart in Industrial Medicine," respectively.—Dr. Robert B. Osgood, Boston, delivered the fourth afternoon lecture at the New York Academy of Medicine, December 7, on "Interpretation of Low Back Pain and Its Treatment," and Dr. Charles G. Kerley the fifth, December 14, on "The Handicapped Child."—Dr. William Wayne Babcock, Philadelphia, addressed the Harlem Medical Association, December 5, on "The Origin of Tumors," and Dr. William R. Williams, on "Facts and Fancies in Regard to the Common Cold."

OHIO

Faculty Changes at Cincinnati.—Thomas J. LeBlanc, Sc.D., has been advanced from associate professor to professor of preventive medicine in charge of a new department of preventive medicine at the University of Cincinnati College of Medicine. Drs. Joseph A. Freiberg and John W. McCammon were promoted to associate and assistant professor, respectively, of orthopedic surgery. Dr. Albert Faller, clinical professor of contagious diseases, resigned and was made emeritus professor.

Health Lectures for the Public.—The fifth annual series of free public health lectures presented jointly by the Cleveland Academy of Medicine and the Albert Fairchild Holden Foundation will begin January 13 with an address by Dr. Gerald S. Shibley, associate professor of medicine, Western Reserve University School of Medicine, on "The Common Cold."—Succeeding lectures will be given by Drs. Russell L. Haden, on "Anemias and Diet"; Marion A. Blankenhorn, "The Art and Science of Diagnosis," and John A. Toomey, "Stopping the Spread of Contagions."

Society News.—Dr. Mark Millikin, Hamilton, was elected president of the Union District Medical Association at its semiannual meeting in Hamilton, October 25. Speakers were Drs. Otto J. Seibert, Cincinnati, on "Intestinal Obstruction"; Charles O. McCormick, Indianapolis, "History of Birth Control," and Harry P. Ross, Richmond, Ind., "Obstetrics and the Laity."—Dr. Thomas C. Sheridan, Dayton, addressed the Warren County Medical Society, Lebanon, November 6, on eczema.—Dr. James C. Walker Jr., Dayton, discussed "Treatment of Fractures of the Forearm" before the Miami County Medical Society, Troy, November 2.—Dr. Eugene A. Ockuly, Chicago, presented a talk on "Changes in the Ureters and Kidneys During Pregnancy" at a meeting of the Hancock County Medical Society, Findlay, November 1.—Dr. Carl S. Mundy, Toledo, spoke on arthritis before the Tuscarawas County Medical Society, November 8.—Dr. Max Thorek, Chicago, addressed the Columbus Academy of Medicine, November 26, on "Advantages of Electrosurgical Obliteration of the Gallbladder Over Classical Cholecystectomy."—Dr. Hugh H. Young, Baltimore, addressed the Montgomery County Medical Society, Dayton, December 7, on "Tumors of the Bladder and Prostate."

Fifty Years in Practice.—Drs. Benjamin R. McClellan and Asa C. Messenger, Xenia, were guests of honor at a dinner in celebration of their completion of fifty years of medical practice, November 15. Dr. Walter M. Simpson, Dayton, was toastmaster. The speakers were Drs. William E. Lower, Cleveland, on "Medical Organization," and Rinaldo M. Hughey, Washington Court House, on "The Doctor and the Community." Dr. McClellan has for many years taken an active part in medical organizations, having served as president of the Ohio State Medical Association in 1906 and on many of its committees. Since 1911, with the exception of a few years, he has been a member of the House of Delegates of the American Medical Association and from 1915 to 1922 he was a member of the state medical board. Dr. Messenger was

for many years superintendent of the Old Soldiers and Sailors Orphans Home, was at one time health officer of Xenia, and since 1922 has been alternate delegate to the American Medical Association. He is a past president of the Greene County Society and of the second councilor district of the state society. The dinner was arranged by Dr. McClellan's sons, Dr. Robert R. McClellan and Mr. S. N. McClellan, and Dr. Messenger's son, Dr. Harold C. Messenger.

OKLAHOMA

Society News.—Drs. William P. Neilson, Enid, and David S. Harris, Drummond, addressed the Garfield County Medical Society, recently, on "Surgical Aspects of Dyspepsia and Vomiting" and "Tetanus," respectively.—E. L. Miley, D.D.S., Oklahoma City, addressed the Canadian County Medical Society, El Reno, November 6, on fractures of the lower jaw.—Dr. Rufus Q. Goodwin, Oklahoma City, addressed the Pittsburgh County Medical Society, October 18, on pulmonary abscess.—Dr. Philip M. McNeill, Oklahoma City, discussed treatment of pneumonia and its complications at a special meeting of the Cleveland County Medical Society, Norman, October 18.

PENNSYLVANIA

Society News.—Dr. William H. Mayer, Pittsburgh, among others, addressed the Westmoreland County Medical Society, Greensburg, December 13, on "Public Reaction to the Future of Medicine."—Dr. Frank H. Krusen, Philadelphia, addressed the Washington County Medical Society, Washington, December 12, on "Physical Therapy for the General Practitioner."—Dr. Henry H. Ritter, New York, addressed the Berks County Medical Society, Reading, recently on "Treatment of Acute Injuries of the Knee Joint."

Philadelphia

Research on Bacteriophage.—Temple University Hospital has established a new department for research on bacteriophage with Dr. John A. Kolmer in charge. Dr. Kolmer recently resigned as professor of medicine at Temple University School of Medicine.

Society News.—Speakers at a meeting of the Philadelphia Pediatric Society, December 11, were Drs. George M. Coates, on "The Tonsil and Adenoid Problem" and Joseph Stokes Jr., "Review of Certain Recent Developments in the Knowledge of Respiratory Infections."—Dr. Jacques Forestier, Aix-les-Bains, France, secretary of the French league against rheumatism, addressed the Philadelphia Roentgen Ray Society, December 13, on "Technic and Diagnosis in the Use of Iodized Oil" and "The Early Stage of Spondylitis Ankylosans."

Pittsburgh

Hospital News.—Montefiore Hospital held its annual scientific day, November 24, with Dr. Tracy J. Putnam, assistant professor of neurosurgery, Harvard Medical School, Boston, as guest clinician and speaker, on "Physiologic Surgery of the Nervous System."

Executive Secretary Appointed.—The Allegheny County Medical Society has appointed Mr. William H. Palmer executive secretary of the society, effective December 1. Mr. Palmer is a graduate of the school of business administration and has also done graduate work at the University of Pittsburgh. He succeeds Mr. Lester H. Perry, who resigned recently to join the staff of the *Pennsylvania Medical Journal*.

Society News.—Dr. William Wayne Babcock, Philadelphia, delivered the annual R. W. Stewart Memorial Address before the Pittsburgh Academy of Medicine, December 11, on "Conditions Influencing Growth and the Formation of New Growths."—Speakers who addressed the Allegheny County Medical Society, December 18, were Drs. George A. Holliday, on "Lymphogranuloma Inguinale"; David Silver, Richard C. Ritter and John A. Heberling, "End Results in Bone and Joint Tuberculosis," and Thomas A. Miller, "Pneumonia."

RHODE ISLAND

Society News.—Dr. George Blumer, David P. Smith clinical professor of medicine, Yale University School of Medicine, New Haven, Conn., addressed the Providence Medical Association, December 3, on "The Importance of Observation and Induction in Diagnosis, with Some Remarks on Mistaken Diagnoses."—Henry F. Vaughan, Dr. P.H., health commissioner of Detroit, addressed the association, November 5, on "The Family Physician and Preventive Medicine," and Dr. John E. Gordon, New York, on "Newer Aspects in the Control of Communicable Disease."

TEXAS

Society News.—Dr. Britton E. Pickett, Carrizo Springs, was elected president of the Texas Public Health Association at its annual meeting in Abilene, recently.—Drs. Robert B. Homan Jr. and William R. Jamieson addressed the El Paso County Medical Society, El Paso, recently, on syphilis of the lung and senility, respectively.—Drs. Theodore W. Kalb and Henry S. Meyer, Houston, addressed the Hardin-Tyler Counties Medical Society, Woodville, recently, on "Excretion Urography" and "The Infant Abdomen," respectively.—Dr. John Potts, Fort Worth, among others, discussed childhood tuberculosis at a meeting of the Tarrant County Medical Society, Fort Worth, recently.—Speakers at a meeting of the Mid-West Texas District Medical Society in Abilene, recently, included Drs. Arthur Bob Alexander, Spur, on "Modern Diagnosis and Treatment of Purpura Haemorrhagica"; Frederick E. Hudson, Stamford, "Relapsing Fever as Seen in West Texas"; Lee E. Parmley, Big Spring, "The High Mortality in Obstetrical Practice in the United States," and Claude B. Leggett, Abilene, "Systemic Diseases and Their Effects on the Eye."—Drs. Lawrence B. Sheldon and Harold T. Nesbit, Dallas, addressed the Morris and Titus county medical societies at a joint meeting in Daingerfield, recently, on "Gastro-Intestinal Hemorrhage" and "The Crying Baby," respectively.—The Dallas County Dental Society will hold its ninth mid-winter dental clinic at Baylor University School of Dentistry, February 4-6.

WEST VIRGINIA

Society News.—Dr. Curtis C. Mechling, Pittsburgh, addressed the Kanawha Medical Society, Charleston, October 23, on "Carcinoma of the Rectum."—At a meeting of the Mercer County Medical Society, Princeton, October 11, Dr. Earl Bennette Henson, Charleston, discussed poliomyelitis and backache and Dr. Weldon M. Harloe, Matoaka, poliomyelitis.—Dr. Joseph Earle Moore, Baltimore, addressed the Parkersburg Academy of Medicine, October 4, on "The Wassermann-Fast Patient."—Dr. James A. McClung, Richwood, was elected president of the Hospital Association of West Virginia at the annual meeting in Morgantown, October 5. Among speakers were Drs. Theodore K. Oates, Martinsburg, on "Sterilization of a Particular Class of Patients" and John E. Ofner, Weston, "Sane Hospitalization and Treatment of the Insane."—Drs. Brinley John and William L. Madera, Morgantown, addressed the Monongalia County Medical Society, November 13, on "Postoperative Paralytic Syphilis" and "Radiation Therapy of Acne Vulgaris," respectively.—Dr. Clint W. Stallard, Montgomery, addressed the Fayette County Medical Society, Oak Hill, November 9, on "Acute Fractures of the Spine."

WISCONSIN

Veteran Physicians Honored at Dinner.—Nine members of the Milwaukee County Medical Society who have practiced medicine for fifty years were guests of honor at a dinner given by the society at the Milwaukee Athletic Club, December 4. They were Drs. William P. Jobse, James J. Cavaney, Leopold Schiller, William H. Washburn, Arthur J. Puls, Charles Zimmermann, James A. Bach, William Sweemer and John W. Fisher. Speakers who felicitated the guests were Drs. Rock Sleyster, Wauwatosa, member of the Board of Trustees, American Medical Association; Charles R. Bardeen, dean, University of Wisconsin Medical School, Madison; Eben J. Carey, dean, Marquette University School of Medicine; Thomas J. O'Leary, Superior, president of the State Medical Society of Wisconsin, and Charles Fidler, president of the Milwaukee County Medical Society. Dr. Arthur T. Holbrook presided and Dr. Bach responded to the tributes.

Society News.—Drs. Sumner L. S. Koch and Loyal Davis, Chicago, addressed the Dane County Medical Society, Madison, November 15, on "Surgical Repair of Injuries Involving Tendons of the Upper Extremities" and "Diagnosis and Treatment of the Injuries of the Peripheral Nerves of the Upper Extremity," respectively.—Dr. John L. Garvey, Milwaukee, was a speaker at the meeting of the Ninth Councilor District Medical Society, Wausau, November 15, on "Problems of Neurology of Interest to the General Practitioner."—Among speakers at the annual meeting of the Grant County Medical Society, Lancaster, October 25, were Drs. William D. Stovall, Madison, on "Present Status of Immunization Against Certain Communicable Diseases" and Donovan F. Ward, Dubuque, Iowa, "Treatment of Appendiceal Abscess."—Dr. George W. Hall, Chicago, addressed the Rock County Medical Society, Beloit, October 23, on diseases of the nervous system.—Drs. Rock Sleyster, Wauwatosa, and George H. Ewell, Madison, addressed the Washington-Ozaukee Counties Medical

Society, Cedarburg, in October on "The Patient with Chronic Complaints" and "Diagnosis and Treatment of Common Diseases of the Rectum and Anus," respectively.—Drs. Alexander T. Nadeau and Clarence H. Boren, Marinette, addressed the Marinette, Florence and Menominee Counties Medical Society, Marinette, November 15, on "Complications of Scarlet Fever" and "Ulcerative Diseases of the Intestines," respectively.

GENERAL

Personal.—Willard Earl Givens, superintendent of schools of Oakland, Calif., has been appointed secretary of the National Education Association, succeeding J. W. Crabtree, who has reached the retiring age. Mr. Givens has been in educational service as teacher and superintendent of schools in Indiana, California and Hawaii since 1906.

Licenses Lost.—Dr. Harriet L. Palmer, Cambridge, announces that her certificate of registration in medicine has been lost. Dr. Palmer, who in private life is Mrs. Bryant, was graduated from Boston University School of Medicine in 1907 and was licensed to practice the following year. Dr. Dorothea May Moore, also of Cambridge, reports that her Massachusetts license has been lost.

Congress on Gastro-Enterology.—The First International Congress on Gastro-Enterology is being planned for Aug. 8-10, 1935, at Brussels, Belgium, under the presidency of Dr. J. Schoemaker, The Hague. The secretary general is Dr. George Brohee, Rue de la Concorde, 64, Brussels. Dr. Max Einhorn, New York, is forming an American committee of which he is chairman and Dr. DeWitt Stetten, New York, secretary.

National Academy of Sciences.—At the autumn meeting of the National Academy of Sciences at Cleveland, November 19-21, papers of medical interest included the following:

Dr. Carl J. Wiggers, Cleveland, Further Observations on Systolic and Diastolic Coronary Flow Under Natural Conditions.
Dr. Anton J. Carlson, Chicago, Criteria of Alcohol Intoxication.
Dr. Alan R. Moritz, Cleveland, Arteriolar Changes in Essential Hypertension.
Dr. Julius M. Rogoff, Cleveland, Present Status of the Adrenal Cortex Problem.
Dr. Torald H. Sollmann and Nora E. Schreiber, Cleveland, The Fate of Mercury in Acute Bichloride Poisoning.

Changes in Status of Licensure.—The Florida State Board of Medical Examiners recently reported the following action:

Dr. Richard B. McFeeters, Cross City, license restored.

The Massachusetts Department of Registration in Medicine reports the following action:

Dr. Oscar Hurovitz, Roxbury, license suspended, November 15, for three months because of gross misconduct in the practice of his profession, as shown by deceit in the case of a patient treated by him in connection with automobile accident liability insurance.

Grants for Research.—The American Academy of Arts and Sciences included among its grants for research the following for medical purposes: Dr. Bret Ratner, New York, \$375 to aid his experiments on asthma in the guinea-pig at New York University and Bellevue Hospital Medical College, and Clarence C. Little, Sc.D., and Charles V. Green, Ph.D., Roscoe B. Jackson Memorial Laboratory, Bar Harbor, Maine, \$750 for care of experimental animals and the preparation and study of microscopic sections of tumors in their work on cancer research.

Results of Examination.—Twenty-five candidates were examined by the American Board of Otolaryngology at its meeting in San Antonio, November 13. Seven were conditioned or failed. During 1935 examinations will be held in New York, June 8, in connection with the meeting of the American Medical Association, and at Cincinnati in the fall, during the meeting of the American Academy of Ophthalmology and Otolaryngology. Prospective applicants for certificates should address the secretary, Dr. William P. Wherry, 1500 Medical Arts Building, Omaha, for application blanks.

News of Epidemics.—An outbreak of fifteen cases of infectious jaundice was recently reported from Greene County, Ohio, centered in Jamestown and Ross township.—Three hundred children in Muscatine, Iowa, were reported to be ill of measles, November 26. In Canton, Ill., 500 children were out of school as a result of an epidemic of measles, it was reported, November 26.—An outbreak of typhoid was reported in November in Lexington, Ky., where eleven cases were found in the vicinity of a spring.—Scarlet fever was widespread in Champaign-Urbana, Ill., in November, causing health and school officials to take special precautions.

Women Physicians' International Meeting.—The triennial meeting of the Medical Women's International Association will be held in Edinburgh in 1937. Subjects for discussion will be "Cancer in Women and Its Prevention" and "Abor-

tion." At the meeting in Stockholm in August 1934 Dr. Alma Sundquist, Stockholm, was elected president. At that meeting subjects discussed were birth control, on which Dr. Marie P. Levinson Warner, New York, led discussion for the Americans, and effects of physical culture on the development, structure and functions of the female body, on which Drs. Bertha Van Hoosen, Chicago, and Bertha S. Stuart Dymont, Stanford University, Calif., led the discussion. About 200 medical women from eighteen countries attended, including thirty from the United States.

Obstetric Meeting.—The Pacific Coast Society of Obstetrics and Gynecology held its annual meeting, November 21-22. The first day was devoted to clinics at the Alameda General Hospital, Oakland, and the second to a scientific program at the Del Monte Hotel, Del Monte. Speakers included:

- Dr. Albert L. Mathieu, Portland, Early Diagnosis of Chorion Epithelioma.
- Dr. C. Frederic Fluhmann, San Francisco, Ovarian Injury as a Cause of Uterine Bleeding.
- Dr. Frank C. Ainley, Los Angeles, The Vomiting of Pregnancy.
- Dr. Norman H. Williams, Los Angeles, The Use of X-Rays in Obstetrics.
- Dr. Clarence A. DePuy, Oakland, Sustained Analgesia in Late Malignancies.
- Dr. Thomas F. Wier, San Diego, Pituitrin and Nausea in Labor.
- Dr. John A. Sperry, San Francisco, Uterine Fistulae.
- Dr. Emil J. Krahulik, Los Angeles, The Rupture of the Membranes Before the Onset of Labor.
- Dr. Karl L. Schaupp, San Francisco, A Study of Prenatal Care from Two Five Year Periods at San Francisco Hospital.
- Dr. Henry A. Stephenson, San Francisco, Critical Analysis of Maternal Mortality.

Medical Program of Science Association.—At the ninety-fifth meeting of the American Association for the Advancement of Science in Pittsburgh, December 27 to January 2, Section N, on the Medical Sciences, will have meetings Thursday, Friday, Saturday and Monday mornings and Monday afternoon. A leading feature of the program will be a symposium on poliomyelitis, in which participants will be Drs. Maurice Brodie, New York; John A. Kolmer, Philadelphia; William Lloyd Aycock, Boston; Noel Paul Hudson, Chicago; Earl B. McKinley and Randall Thompson, Sc.D., Washington, D. C. Two sessions will be devoted to a symposium on "The Chemistry and Metabolism of Sulphur-Containing Compounds of the Body." Dr. Cyrus C. Sturgis, Ann Arbor, Mich., vice president for the section, will deliver his official address at a general session Thursday afternoon; his subject will be "Review of the More Important Recent Advances in the Study of Blood Diseases." Dr. William A. White, Washington, D. C., will speak Thursday evening at Carnegie Music Hall. His subject will be "Man the Great Integrator."

Society News.—Dr. Thomas A. Burcham, Des Moines, was chosen president elect of the Radiological Society of North America at its annual meeting in Memphis, December 3-7. Dr. Lloyd Bryan, San Francisco, was installed as president and Dr. Donald S. Childs, Syracuse, N. Y., reelected secretary. The place of the next meeting has not been decided. Among features of the meeting was the Carman Lecture honoring the memory of the late Dr. Russell D. Carman, Minneapolis, a former president of the society. The lecture was delivered by Dr. Byrl R. Kirklín, Rochester, Minn., on "Some Phases of Radiological Diagnosis of Gastric Cancer."—Dr. Morris Fishbein, Chicago, editor of *THE JOURNAL*, will speak at the annual luncheon of the American Student Health Association at its annual meeting in New York, Thursday, December 27, on "The Nature of Medical Organization." Among other speakers will be Drs. Esmond R. Long, Philadelphia, on "Tuberculosis in College Students"; Abraham A. Brill, New York, "The Psychiatric Approach to the Problem of Homosexuality"; and Theophile Raphael, Ann Arbor, "The Mental Hygiene Department of the University of Michigan." The meeting will continue through Friday. Dr. Fishbein will preside at the evening banquet, at the Waldorf-Astoria, of the Phi Delta Epsilon Medical Fraternity, which will hold its thirty-first annual conclave in New York, December 29.

CANADA

Control of Medical Broadcasts.—The Canadian Radio Commission is working with the Department of Pensions and National Health in controlling broadcasts of "patent medicines," the *Canadian Medical Association Journal* reports. The department censors all script submitted, but there is no routine check of the broadcasts to determine whether the censored script is followed. It was suggested that physicians report to the commission apparent breaches of the permissible latitudes.

Gift for Convalescent Home.—The Toronto General Hospital is to receive a bequest of about \$300,000 from the widow of the late Dr. George A. Bingham to build and maintain a home for convalescent patients as a memorial to him.

Dr. Bingham, who died in 1922, was professor of clinical surgery and clinical anatomy at the University of Toronto Faculty of Medicine. Mrs. Bingham's will, recently filed for probate, also gave \$2,000 to the Hospital for Sick Children, \$1,000 to the Home for Incurable Children, \$25,000 for the equipment of a hospital at Matheson, Ont., and \$5,000 to the Alumni Federation of the University of Toronto for needy students in the Faculty of Medicine.

New Hospital Dedicated.—The dedication of the new Jewish General Hospital of Montreal took place October 8. Honor guests were His Excellency, the Earl of Bessborough, governor general of Canada; the Hon. L. A. Taschereau, prime minister, Province of Quebec; the Hon. L. Athanase David, Provincial Secretary of the Province, and the mayor of Montreal, M. Camillien Houde. The new hospital, begun in 1932, was recently completed at a cost of about \$1,250,000. The following physicians have been appointed to the staff of the new institution: Drs. Joseph Kaufmann, medicine; Edward W. Archibald, surgery; James Robert Goodall, gynecology; Alton Goldbloom, pediatrics; Abraham O. Freedman, otolaryngology; Jacob Rosenbaum, ophthalmology.

Faculty Changes.—Dr. John A. Gunn, Winnipeg, became professor of surgery this year at the University of Manitoba Faculty of Medicine, succeeding Dr. Brandur J. Brandson, and chief surgeon of the Winnipeg General Hospital. Dr. Brandson retired with the title of professor emeritus in surgery and Dr. Charles Hunter, professor emeritus in medicine. Dr. George I. Boyd, assistant professor of anatomy, resigned to go to Leeds University, England, and was succeeded by Dr. Larus A. Sigurdson as lecturer.—Dr. Samuel Ernest Whitnall, chairman of the department of anatomy at McGill University Faculty of Medicine, Montreal, has resigned to become professor of anatomy at the University of Bristol, England.—Dr. Ray F. Farquharson, Toronto, succeeded Dr. Robert D. Rudolf, head of the department of therapeutics and assistant in medicine at the University of Toronto Faculty of Medicine. Drs. Neil E. McKinnon and William F. McPhedran are new assistant professors of hygiene and epidemiology and of medicine and clinical medicine, respectively.

Society News.—The laboratory section of the Canadian Public Health Association held its annual Christmas meeting, December 20-21, at the Royal York Hotel, Toronto. Among the speakers were Dr. George W. McCoy, director, National Institute of Health, U. S. Public Health Service, Washington, D. C., on amebic dysentery.—Dr. Allan R. Dafoe, Callender, Ont., was guest speaker at a meeting of the Academy of Medicine of Toronto, December 4; his subject was "A Medical Fairy Tale."—Dr. Austin B. Schinbein addressed the Vancouver Medical Association, December 4, on "Tumors of the Breast."—The Western Ontario Academy of Medicine furnished the program of the Toronto Academy of Medicine, November 6, with the following speakers, all of London: Drs. Frederick J. H. Campbell, "Undulant Fever"; H. Murray Simpson, "Treatment of Lung Abscess"; Earle M. Watson, "Wheat Germ Oil (Vitamin E) Therapy," and Madge T. Macklin, "Is the Increase in Cardiovascular Renal Disease Real?" Dame Janet Campbell, London, England, addressed a special meeting, November 16, on "Developments in Community Health Work as it Affects the Medical Profession."

Government Services

Rear Admirals in Medical Corps

Captains John B. Dennis and Charles St. John Butler have been recommended for appointment to the grade of rear admiral in the medical corps. They will fill the vacancies created by the retirement of Rear Admiral Charles P. Kindleberger and Rear Admiral James C. Pryor within the next few months, according to *Military Surgeon*.

New Head of Children's Bureau

Miss Katherine F. Lenroot, who has been acting chief of the Children's Bureau of the Department of Labor since the resignation of Miss Grace Abbott July 1, was appointed permanently by the President, December 1. Miss Lenroot, a daughter of former Senator Lenroot of Wisconsin, has been on the staff of the bureau for twenty years and assistant chief since 1922. She served as research secretary of the delinquency committee of the White House Conference on Child Health and Protection and was chairman of the United States delegations to the fifth and sixth Pan-American child congresses. She is at present president of the National Conference of Social Workers.

The Scientific Detection of Crime

A scientific laboratory is to be added to the equipment of the Metropolitan Police College, where candidates for the higher posts undergo training. The main function of the officer in charge of the laboratory will be to assist in the investigation of criminal cases, to give instruction in scientific methods of crime detection to the students of the college, and to undertake research work. Dr. James Davidson of Edinburgh University has been selected for this appointment. At first there was a difference of opinion whether the resources of a scientific laboratory should be restricted to meeting the needs of cases under investigation or also to teach young officers taking courses at the college. Similar laboratories in other parts of the country are in the main used for problems in connection with crimes calling for scientific solution. It has been decided, however, that Dr. Davidson's services will be available when research or experiment is required, and detectives will have the benefit of his services when engaged on cases.

The Change in the Treatment of Mental Defectives

At a conference of the Central Association for Mental Welfare, Sir Leslie Scott, the president, contrasted the present treatment of mental defectives with that of the past. This association when instituted twenty-one years ago had \$50 in the bank; today its income is \$75,000 a year in the form of grants and payments by government departments and local authorities. There was a disposition of a large section of the public to look on all problems of mental health with aversion, and it had been difficult to get local authorities to understand that the problem of mental defectives was of national importance. The necessity of making life inside an institution like life outside had been realized. The medical superintendent went outside to visit clinics and hospitals, and into institutions came teachers of crafts, leaders of Girl Guides and of Scouts, and instructors of games and physical exercises, bringing new ideas and preserving contact with the mentally normal. Many of the patients went regularly on parole and spent a holiday in camp, which had developed into holiday homes and tours. Clubs were one of the remarkable developments of recent years and had been developed in many large centers for youths and elders, and there were hostels for working boys and girls from which, after being trained in institutions, they could go out to daily work. All progress seemed to be in the same general direction, away from the old theory of incarcerating defectives in asylums or segregated groups and toward a policy of bringing them as much as possible in touch with their normal fellows.

VOLUNTARY STERILIZATION OF DEFECTIVES

Sir Hilton Young, minister of health, a guest of the association at a luncheon, suggested that it should bring the advantage of its experience to bear on the difficult question of voluntary sterilization of the unfit. The report of the departmental committee in favor of voluntary sterilization supplied the raw material, and it would be of great value if public opinion might be informed and a national conscience created in that matter and so enable the government to take action. Sir Leslie Scott said that the attitude of the association toward sterilization was one of general support to the recommendations of the departmental committee. It had joined in forming a joint committee to make those recommendations known throughout the country and to consider the best way in which they could be passed into law.

Vacuum Packing an Alternative to Cold Storage

An alternative to the cold storage system for the transport of perishable foodstuffs over great distances without deterioration was explained at a luncheon attended by the New Zealand high commissioner and the agents general of New South Wales, Victoria, Queensland, Tasmania and West Australia. The system that has the trade name of Vacpac has been tried in all climatic conditions for four and one-half years, and regular consignments of butter, cheese, honey, meats, fruit pulp and fruit juices have been successfully transported from New Zealand to London, India, China and elsewhere for three years. The goods are packed by a vacuum process, which does not involve heating or the use of preservatives, the cases being then conveyed as general cargo and not in cold storage. It is claimed that the foodstuffs reach the consumer in the same state of freshness as when packed, unaffected by climatic changes or by such risks as loss of flavor, aroma or color. On the other hand, the maturing of cheese, for example continues unchecked. Also when the goods are unpacked the rate of deterioration is below normal. Vacuum-packed products cost a little more than those transported by other methods, but they bring higher prices.

While the principle of food preservation by exclusion of air and moisture is not new, it has been adapted for the first time to transport across the world. The system is at present confined to New Zealand, which has three factories, but it is now proposed to make it available for all the food-producing countries in the empire. Sir James Parr, high commissioner for New Zealand, a country that has sent more butter to the English market than any other country in the world, viewed the new venture with interest.

The Drug Traffic: Growth of Clandestine Factories

At a meeting in Geneva of the Advisory Committee on Traffic in Drugs of the League of Nations, it was stated that although the steady flow of drugs from licensed factories into illicit traffic had much decreased, clandestine factories were springing up and becoming a more abundant source of supply than the authorized factories used to be. The committee during its present session will study the institution of a specialized police force for the detection and closure of these clandestine factories and the effective combating of illicit traffic. It discussed the issue of passports and visas to notorious traffickers. Some of these move about freely, and it has not been possible to limit their travels and prevent them from setting up clandestine factories in countries where the abundance of raw material would render these factories particularly dangerous.

Cotton Spinners' Cancer: Specification of a Safe Oil

Important work has been done at the research laboratories of the Manchester Cancer Committee under the direction of Dr. C. C. Twort with a view to prevention of the disease known as mule spinners' cancer (due to irritation of the scrotum with the lubricating oil used). Dr. Twort has devised a standard specification for safe mineral lubricating oil, based solely on its physical characters. Mineral lubricating oils should have a refractivity below 5,520, when the specific gravity is above 0.985, or a refractivity below 5,550, when the specific gravity is below 0.985. In calculating the refractivity the density at 60 F. is used. It appears that some mineral oils are much more carcinogenic than others, and all of them except white oils and spirits have to be viewed as potentially carcinogenic. Dr. Twort can now arrange the chief world supplies of oil according to their cancer generating powers. The least harmful oils are Russian, and those from Pennsylvania and Texas come next, while the Scottish shales are highest, more than forty-five times as potent as the Russian. But oils of varying potency can be obtained from every single area, so that too much stress must not be laid on the origin.

Bacillema in Tuberculosis and Other Diseases

During the last few years, the Vienna bacteriologist Loewenstein has published a number of observations in which he reported that in certain diseases, heretofore not considered as of tuberculous origin, cultures made from the blood yielded positive results. Tubercle bacilli were found, according to Loewenstein, in such diseases as acute and chronic rheumatism and dementia praecox.

Two papers have appeared here recently, one by A. Saenz of the Pasteur Institute and another by Debré, Saenz and Broca, in which it is shown that the majority of the positive blood cultures were due to errors in technic. Saenz has paid especial attention to the question as to how these errors arise. In his article in the June *Annales de l'Institut Pasteur*, Saenz states that, so far as culture mediums for isolation of the tubercle bacillus are concerned, the medium of Loewenstein as well as that of Petragani are preferable to all others.

The use of a 20 per cent solution of sulphuric acid, to destroy organisms producing contamination of the cultures and thus to permit the tubercle bacillus to develop, does not affect the vitality of the human, bovine or avian type of the bacillus of tuberculosis. An important source of error has been that many investigators who report positive results in blood taken from diseases heretofore considered as bearing no etiologic relation to tuberculosis base their reports on finding microscopic colonies after scraping the surface of the medium when no macroscopic growth is present. Such colonies contain acid-fast bacilli, but the latter are only groups of dead bacilli, which can be found in the rubber tubing or in the various solutions that have been employed in preparing the culture medium or stains.

Saenz maintains that results can be interpreted as positive only when the colonies develop after being reinoculated on other tubes and also if they give positive results in guinea-pig inoculation or on reinoculation from the first inoculated guinea-pig into others.

Colonies that appear very late are not tubercle bacilli, as stated by Loewenstein, but paratubercle bacilli. In cultures made from the blood of 500 cases of from various forms of tuberculosis there were ten (1.2 per cent) in which there was macroscopic growth. Of these ten, there were three due to saprophytic acid-resistant bacilli which did not possess the characteristic pathogenic properties of the tubercle bacillus when inoculated into guinea-pigs.

Of fourteen cases in which the blood of infants and adolescents was studied at the period of earliest invasion by the tubercle bacillus, six were found faintly positive, one on the Loewenstein culture medium and five only on guinea-pig inoculation. The finding of the bacilli in the blood precedes clinical evidence of localization in the lymph nodes, lungs and spleen. Cultures from the blood in ninety cases of acute and chronic rheumatism and from ten cerebrospinal fluids were all negative.

Guinea-pigs must be kept under observation for a period of six months after inoculation. In the six cases in which positive results were obtained in guinea-pigs inoculated with blood from cases clinically diagnosed as tuberculosis, the culture was negative. This shows the superiority of guinea-pig inoculation in cases in which the culture is negative.

The early invasion of the blood by tubercle bacilli in children is composed of relatively few bacilli and has no prognostic significance.

Reorganization of the Pasteur Institute

The death of Professor Roux, director, a few days after that of Professor Calmette, assistant director, has necessitated a complete reorganization of the executive committee of the

Pasteur Institute. The institution has grown to an incredible degree since its foundation by Pasteur, who gathered around him distinguished workers such as Roux, Calmette, Metchnikoff and Yersin. At the time the laboratories began to expand and increase in number, the clinical side developed as the result of the discovery of serotherapy. The work of Roux on diphtheria antitoxin and of Calmette on the various aspects of tuberculosis are only two of the numerous achievements of this remarkable band of investigators, following closely the brilliant example of their leader, Pasteur.

Dr. Louis Martin has just been appointed director and Dr. G. Ramon assistant director. The former was a co-worker of Roux in diphtheria research and is well known for his investigations on other subjects, such as icteriohemorrhagic spirotrichosis, trypanosomiasis and the experimental production of tuberculous meningitis in rabbits. Ramon discovered the method of utilization of diphtheria antitoxin (after treatment with formaldehyde and heat) for purposes of immunization as anatoxin. The executive committee now includes men who were all pupils of Pasteur, such as Bordet, Bertrand, Yersin, Borrel and Mesnil. With such a distinguished group to aid Martin and Ramon, the institute will be assured its rank as one of the leaders in the world of research.

Center for Citrated Blood for Transfusions

In Bordeaux a center has been established in the public hospitals in which flasks containing 300 cc. of blood, kept in liquid form with sodium citrate solution, is placed at the disposal of physicians in place of grouped donors. The blood can be used, if kept in a refrigerator, during a period of two weeks or even longer, after it has been received from professional donors or from volunteers. One thus has always a thoroughly tested and grouped blood, ready in case of emergency.

Oct. 15, 1934.

Population Movement in Germany

The population statistics recently compiled for the first quarter of the year 1934 are interesting. The preliminary numbers were:

	First Quarter 1934	First Quarter 1933
Marriages	138,438	94,686
Viable born	281,024	246,915
Stillborn	8,215	7,601
Dead (but not stillborn, including infants up to age of 1 year)	193,134	221,374
Excess of birth over death rate	87,890	25,541

The sparse increase in the frequency of birth, which became visible first in the cities in the second half of 1933, had grown into a noteworthy increase from the beginning of the year 1934. In rural districts only a slight increase in the incidence of births was found.

Statistics on viable born infants per thousand inhabitants for the complete year show:

Quarter	1913	1932	1933	1934
First	27.2	16.0	15.2	17.2
Second	26.8	15.4	14.9	
Third	27.3	14.6	14.6	
Fourth	26.3	14.1	14.0	
Average	26.9	15.1	14.7	

The decline in the incidence of induced abortions is cited as the main cause of the constant increase in the number of births.

The increase in marriages during the second quarter of 1933 definitely contributed to the great increase in births during the first quarter of 1934; the marked increase in the incidence of marriage in the third quarter of 1933 might have also aided the 1934 birth rate to a slight degree. Whether this is actually a revival of the people's will to propagate will be definitely determined on the basis of the exact total number of births

recorded during the course of years of marriage. The excess of the birth rate over the death rate came to 87,890 in the first quarter of 1934; that is, 5.4 to every 1,000 inhabitants. As a result of the increase of births and the simultaneous decline in mortality, the excessive birth rate was three and one-half times as large as in the first quarter of 1933, in which it came to 25,541; that is, 1.6 to every 1,000 inhabitants. Additional statistics have been compiled for Berlin. The birth incidence for Berlin in July 1934 amounted to 13.9 to every 1,000 inhabitants, in July 1933 to 8.6, thus a rise in the lapse of a year amounting to 63 per cent. This would have been considered impossible until recently, since Berlin (together with the scarcely larger numbers of Vienna) lead the world cities in a low birth rate; Paris and London had half as many more, New York double as many births, Moscow and Tokyo two and one-half times as many. There is also a striking difference in the birth rate for the total number of large cities in Germany: It was 10.7 in July 1933 and 15 in July 1934. Whether the danger of a dying population, which unquestionably existed, has been set aside cannot be answered with any degree of positivity. But in the light of Germany's birth rate for the year 1934 it may be said that there is no longer any danger of a dying population. At the same time it has been taken into consideration that the death rate grows as a result of an increase in the middle and advanced age groups. The total number of large cities, including Berlin, show a birth incidence of only 40 per cent, and rural communities an incidence of 35 per cent, as opposed to the previously mentioned 60 per cent birth incidence of Berlin. According to Prof. Julius Wolf, the birth rate for the year 1934 amounted approximately to 20 per thousand inhabitants as opposed to 14.7 in 1933, so that Germany is again ahead of France and England by a ratio of 16 to 15. The birth rates for Italy (23:1,000) and Poland (26:1,000) are even higher but are beginning to decrease. The number of illegitimate births showed no change during the rise in the birth rate whereas the number of legitimate births naturally rose. The number of illegitimate births in the large cities of Germany amounted to 1.4 per thousand inhabitants from January to July 1934, to 1.3 per thousand in the same period of 1933, and to 1.5 per thousand in the same period of 1932.

The number of marriages in the large cities during the first quarter of 1934 was considerably greater than in the rural districts. In communities of 15,000 or more inhabitants, approximately 26,500, or 58 per cent, more marriages were performed in 1934 than during the preceding year, whereas in the other communities the number came to only 17,200, or 35 per cent.

During the first quarter of 1934 the rate of mortality was significantly lower than in the first quarter of 1933, because the grip epidemic during the latter year had resulted in so many deaths; the regression amounts to 26,560, or 13.3 per cent. To every thousand inhabitants there were only 10.7 cases of death. (The rate for 1933 was 12.4 to 1,000); 6,450 persons less died of grip in 1934 than in the first quarter of 1933 (only 1.5 to every 10,000, against 10.4). Also the number of cases of death from bronchitis and pneumonia went back to 2,300 (9 against 11.3 to every 10,000 inhabitants), the same as in cardiac diseases, in which 900 less cases of death were recorded than in the first quarter of 1933. Likewise there are fewer cases of death due to senile debility and tuberculosis. Furthermore, the mortality due to death and homicide, which is essentially more important than the figurative effect, decreased from 215 to 101.

The Number of Tooth Brushes Among Students

The public health office of the German Hygiene Institute of Dresden recently made an extensive inquiry in German schools on how many students possess tooth brushes. The results are as surprising as deplorable. Of 7,000 schools with 900,000 students, 42.4 per cent owned their own tooth brushes, 18.2 per

cent had a family tooth brush and 39.4 per cent had none. To this must be added that close to 5,000,000 school children at least do not use their own tooth brush.

Investigation of Incidence of Death in Syphilis

The official German statistics on the causes of death in the reich contain only a small fragment of the actual number of deaths due to syphilis, because of the difficulty of diagnosis and of determining the exact cause of death and because the physician frequently refuses to reveal the confidence of his patient. Consequently the only way at present to determine definitely the death rate of syphilis is to compile the total results of the most reliable investigators. This was done by Dr. H. Gottschalk of Berlin, of the German Society for the Prevention of Venereal Diseases. Thus, for example, Nuremberg, following the model set by Switzerland since 1925, had a confidential death record, in which physicians reported the contributory causes of death. The combined record of the causes of death in Magdeburg for the years 1926 to 1930 was not limited to the primary diseases but extended to the secondary diseases and attempted to clarify indefinite diagnoses by means of inquiries into each individual case. In addition to this a careful report on necropsies was made at the Rudolf Virchow Hospital of Berlin. The greatest difficulty lies in determining how often syphilis is the immediate cause of death in cases in which it is found side by side with other primary diseases. By taking this difficulty carefully into account, the death rate for acquired syphilis gathered from the metropolitan sources mentioned may be cited as from 3 to 4 to each 10,000. A careful determination of the German death rate for syphilis comes to 15,000. According to the Magdeburg statistics, the number of deaths due to congenital syphilis for Germany as a whole amounts to from 3,000 to 4,000 annually.

SOUTH AFRICA

(From Our Regular Correspondent)

CAPE TOWN, Nov. 2, 1934.

The Annual Medical Congress

The twenty-eighth South African Medical Congress was held at Pretoria, October 1-6. Pretoria, the administrative capital of the union, is at this time of the year at its best. Its heat and humidity are always trying, but in October neither is too great to inconvenience visitors, who are always thrilled by the amazing beauty of the blue jakaranda trees, which line the principal streets and are just beginning to blossom. A congress at such a center is distinguished less by the excellence of the papers and the keenness of the discussions than by the social amenities, and this year's gathering was no exception. There was so much to see that the sections and the plenary meetings were badly attended. A feature of this year's meeting was the part taken in the discussions by the staff of the Veterinary College at Onderstepoort, an institution made famous by the researches of Sir Arnold Theiler. His disciples have been inspired by his zeal and have evolved an admirable department for the study of comparative medicine. They showed numerous pathologic and bacteriologic preparations, exhibiting the various stages of lesser known anemias in wild animals. Dr. A. Pijper, another research worker, showed his preparations illustrating tick-bite fever and the results of his successful attempts to inoculate this disease. The president of the congress, Sir Edward Thornton, chief medical officer of health for the union and secretary to the department of public health, in his address dealt with the public health and foreshadowed developments in health legislation in the near future. It is doubtful whether the present government is likely to grapple with public health difficulties of importance, for it has so far proved itself a wholly opportunist administration not greatly interested in anything but the desire to retain power. Public health, unfortu-

nately, has never been a matter of political interest, and it is unlikely that it will ever be seriously considered unless the union is fortunate enough to get an administration that has the knowledge and the energy to disregard the prejudices and jealousies of the provinces and to regard the problems on a broad, scientific basis. Sir Edward tactfully pointed out these truths when he remarked that national health cannot be obtained unless and until the people assent to it, and that it certainly cannot be secured, still less imposed, by parliament or the local or central authorities unless the people understand the necessity for it.

Payment of Hospital Staffs

In former letters I have referred to the resolution by the medical association that honorary staffs should be paid for services rendered to pauper patients in all government hospitals except the two large teaching hospitals at Cape Town and Johannesburg. The resolution was passed on to the branches with a hint that the time is now opportune to enforce payment. There has been some hesitancy in strongly and effectively backing up the policy that has been decided on. This is due to the fact that many practitioners cannot get away from the feeling that they would be acting contrary to the tradition and spirit of the profession by asking for payment for services given to the sick poor. It is not generally recognized that the sick poor are a charge on the state here and that the doctor, being a taxpayer, not only already does his fair share toward their support but is additionally taxed in free service and special professional taxation. However, these arguments are now making some impression, and the majority of hospital boards are quite willing to meet the profession on this matter. In two provinces, too, the provincial administrations that are entrusted with hospitalization are willing to concede payment. In the Cape Province, however, the administration refuses to recognize the principle of payment, although in practice it already pays certain members of honorary staffs for work formerly done by these members gratuitously. It is suggested that a basic charge of £1 be made for every pauper inpatient and that the sum total of these charges be divided among the honoraries for them to do with it as they please. It is impossible, however, to formulate a general scheme applicable to the whole union, and for that reason the association has wisely left branches free to discuss the matter from the local point of view and to make such suggestions as seem to fit their peculiar circumstances. Meanwhile opinion in the profession is hardening in favor of some sort of state medical service. In view of the sparse white population and large native areas, some kind of subsidized medical service seems inevitable in the near future.

A Journal of Scientific Research

The medical association has recently published the first number of the *Quarterly Scientific Journal*, which is an extension of the ordinary medical journal, devoted wholly to articles on original research work. The first issue, which contains ten articles, reaches a high standard. Among the articles that show proof of original research are Dr. Cheetham's on premature artificial systoles in the baboon, Dr. I. Shore's on the spinous processes of the cervical vertebrae found in the skeletons of the European and the South American native, and Dr. McCay's on the treatment of bacillary dysentery by bacteriophage. It is proposed to issue the quarterly for the present at least as a number of the bimonthly journal, but in course of time it will no doubt obtain an independent existence.

Personals

The paleontologist Dr. Robert Broom has been elected an honorary member of the Medical Association of South Africa, an honor that he shares with four other colleagues. Dr. Broom, the only medical F.R.S. in this country, practiced as a general

practitioner for many years after resigning the professorship of zoology at the University of Stellenbosch. He is no longer in practice, having recently been appointed curator of the paleontological department of the state museum at Pretoria. Incidentally, Dr. Broom is an authority on the English artist Constable, of whose work he possesses some admirable examples.

The University of the Witwatersrand has conferred the degree of Dr. Litt. honoris causa on Dr. C. Louis Leipoldt, in recognition of his work as an Afrikaans poet and playwright. He has published some ten plays and four volumes of verse, which have been well received by the critics, and his work has been instrumental in obtaining for Afrikaans the recognition that it lacked for many years. He is lecturer in pediatrics at the New Somerset Hospital, Cape Town, and one of the officials of the medical association.

Deaths

Dr. F. A. Saunders of Grahamstown, one of the oldest practitioners, died in August; he took a great interest in military matters, fought as a combatant in several Kaffir wars, and commanded a regiment in the Boer war.

Dr. D. M. Maciver, died of streptococcal septicemia in August; he was a general practitioner who qualified in Aberdeen in 1898.

Dr. E. S. Towert, a senior practitioner, who qualified at Edinburgh in 1890, died at Johannesburg.

Dr. P. R. Zinn, originally an American citizen, who qualified as an M.D. in New York in 1914, died at Cape Town; he practiced in the country but had sold his practice two years ago with the intention of proceeding overseas to specialize.

ROME

(From Our Regular Correspondent)

Oct. 15, 1934.

Draining the Marshes in Agro Pontino

Prof. Giuseppe Sanarelli, senator, and director of the Institute of Hygiene of the University of Rome, has studied the new sanitary conditions in Agro Pontino. He reports the results of two observations in the *Rassegna italiana* and in the *Annali d'igiene*. Returning to Agro after an absence of six years, Professor Sanarelli found it completely transformed, the tremendous work of draining the marshes having been long under way. The draining of the marshes has built a foundation for the new province of Littoria. More recent medical studies have cast light on the way in which malarial lands may be reclaimed, and modern knowledge of entomology has made possible the long stay of thousands of workers in localities infested with malaria mosquitoes.

Fear was expressed that the Pontine region may continue to be infested by malaria despite the costly work of hydraulic, agrarian and reclamation work in this territory. According to Professor Sanarelli, it would be an exorbitant pretension to believe that individual cases of malarial infection could be avoided during protracted work in a territory which has been malarial for centuries and in which during recent years approximately 80,000 workers have labored in shifts. From official studies quoted by Professor Alessandrini, director of the public health service in Agro Pontino, it shows that in August 1933 the cases of malaria were 2.09 per cent and the mortality in relation to the population was 0.3 per thousand.

Missiroli and his collaborators have recently demonstrated that reclamation operations in malarial zones, by occasioning changes in the hydrographic aspect as well as in the physico-chemical constitution of the soil, thereby producing great modifications in the local flora and fauna, little by little also modify the growth of the anopheline larva. As a result of this the anopheline species that are wont to feed on human blood, such as *Anopheles maculipennis*, *A. labranchiae* and *A. elutus*, are gradually replaced by other anopheline species, such as

A. maculipennis-typicus, *A. atroparyus* and, above all, *A. maculipennis-messae*, which thrive on beasts and have little contact with man. The study of various species of anopheline mosquitoes has therefore cleared up the hitherto inexplicable matter of how simple variations or artificial telluric modifications, by changing the local anophelism, cause either the total disappearance or singular persistence of malarial epidemics in some regions, especially the northernmost regions of Italy and of Europe. Recent entomological studies have thus corroborated the truth of the old saying "the plow conquers malaria."

Commemoration of Bartolomeo Eustachio

Professor Visco, director of the Institute of Physiology of the University of Rome, presided at the commemoration of Bartolomeo Eustachio. After reviewing the development of the natural studies by the philosophers of Greece up to the fifteenth century, he showed how the concept of biology was gradually formed. He illustrated the state of knowledge on this subject during the century of Leonardo da Vinci. Bartolomeo Eustachio stands out in the field of anatomy and physiologic research. A great scientific dissension existed between him and Andrea Vesalio, which for more than fifty years divided European biologists into two fields of bitter dispute. Professor Visco found from his examination that the figure of Eustachio dominated that of Vesalio. While the latter appears only as a man of his century, Eustachio stands with Leonardo da Vinci and Galileo in anticipating modern biology.

National Congress of Stomatology

The Italian Stomatologic Federation held its National Congress in Milan and Como under the direction of Professor Lippo. Prof. Amedeo Perna of the University of Rome read a paper on "The Force of Italian Odontologic Legislation and Its Influence on the Process of Odontologic Legislation Throughout the World." The following resolution was adopted: That professional practice except in cases of dire need be exclusively the property of those who possess the title of specialist, as approved of by the specialized postgraduate schools. Professor Palazzi of Pavia presented a paper on "Biology, Constitution and Metabolism in Diseases of the Dental Pulp and in Paradental Diseases." The literature on this subject was very poor, with the exception of a recent work by Fischer of Hamburg. It was in 1922 that Graeff was able to find the anatomic signs of sepsis in an inferior premolar of a patient who had recurrent endocarditis. Such infections have taken a particular turn toward constitutional diseases of metabolism and those of microbic etiology. Professor Pende, senator and clinical physician of Genoa, spoke on the relation of endocrinology and dental alterations. He states that dental diseases cannot be understood without a sufficient knowledge of the constitution of the subject. This constitution, as is well known, is dominated by the function of the sympathetic nervous system. Thus the study of the action of hormones on the dental system is of fundamental interest to the understanding and reasonable treatment of diseases of the teeth. The most definite action is that of the thyroid, of the genitalia, and of the insular tissue of the pancreas. A good set of teeth corresponds to a well functioning thyroid in conformation, disposition and vitality; when the thyroid functions poorly, the teeth are irregular, poor in enamel and subject to caries and to incrustations of tartar. But when the action of the genital hormones is taken into consideration, contrary to what most authors believe, it is not the functional insufficiency but the hyperfunction that is harmful to the preservation of the teeth. Thus, with respect to the pancreas, metabolic disorders such as hyperglycemia and the tendency to diabetic adiposis constitute an early sign of paradentosis with early denudation of the teeth. The treatment of the area predisposed to caries or

to other dental diseases derives practical importance from these conceptions. The author does not believe in the so-called recalcifying treatment but only in treatment that reinstates the hormone equilibrium and the acid-base equilibrium of the organism. Prof. Roberto Mori of the University of Rome dealt with forensic hygienics of dentistry, enlarging on the subject of the loss and weakening of teeth in relation to the dispositions of the laws in force and to industrial accidents. The author stated that the evaluation by the expert of the damage derived from lesions or loss of teeth should be regulated by law.

Diseases of Sulphur Mine Workers

Sorge and Columba of Catania have done research on diseases of the respiratory organs of workers in sulphur mines. They found that, of 150 persons examined, 129 showed roentgenologic signs of pneumofibrosis, progressing from the hilus to the periphery of the lung. In most cases the lesions were limited to a thickening of the hilar shadows and of the vasculo-bronchial striae; in some, basal thickening was found, whereas others showed a diffuse micronodulation, recalling the classic signs of silicotic pneumoconiosis. Thirteen roentgenograms showed pleural involvement of a productive fibrotic type. Parenchymal changes consisting principally in emphysema and in bronchiectasis are associated with interstitial lesions. According to Sorge and Columba, interstitial lesions are due to inhalation of powder, while the parenchymal lesions are due to inhalation of sulphuric vapors. Considered as a pneumoconiosis, the disease of sulphur mine workers is particularly benign in character both in its gradual development and in the total lack of predisposition to pulmonary tuberculosis.

Dr. Novaro Is Dead

Dr. G. F. Novaro, a senator and professor emeritus of surgical clinics, died in Diano Marina. He was the first to perform, in Italy, hysterectomy in cancer of the uterus, the operation of the vesicovaginal fistula and the transplantation of the ureters into the rectum and on the bladder. He was director of the Istituto di Clinica Chirurgica of Siena, then of the same institute in Bologna and finally in the same institute in Genoa. He made important contributions to surgery, on the removal of cerebral tumors, the removal of the maxilla by the intra-oral route, and resection of the thyroid.

Marriages

WILLIAM VICTOR BRANFORD, Dillon, S. C., to Miss Lucile Love Bryant of Nichols at Fredericksburg, Va., November 29.

MARY SUE TIPTON MULLINS, New York, to Mr. Edwin Charles Jolliffe in London, England, August 29.

DOUGLAS B. KENDRICK JR., Atlanta, Ga., to Miss Dorothea B. Reynolds of Hagerstown, Md., November 17.

AUBREY BERNARD LEE, Birmingham, Ala., to Miss Ruby Nelle Parmer of Quincy, Fla., November 19.

JOHN D. LAMON JR., Albuquerque, N. M., to Miss Mabel Cahoon of Roswell, N. M., September 6.

JACK CHARLES WARBURTON, Paterson, N. J., to Miss Marguerite Zeller of Plainfield, November 24.

ROBERT GRAHAM FERRELL JR., Milledgeville, Ga., to Miss Nida McGehee of Macon, November 3.

JAMES B. GILLESPIE, Urbana, Ill., to Miss Ruth H. Brown of Norwich, N. Y., November 10.

LOUIS ROCCO PANIGROSSO, Raritan, N. J., to Miss Geraldine Iannaconi of Brooklyn, July 4.

JOHN A. WERTZ, Manning, S. C., to Miss Eunice Orr of Pendleton, November 29.

WILLIAM H. MAYER to Miss Virginia Sutton, both of Pittsburgh, November 3.

LESLIE H. REIMERS, Chicago, to Miss Margy Ebaugh of Akron, recently.

Deaths

Theobald Smith, Princeton, N. J., director emeritus of the Department of Plant and Animal Pathology, Rockefeller Institute for Medical Research, died, December 10, of carcinoma of the intestine and heart disease, aged 75. Dr. Smith was born in Albany, N. Y., July 31, 1859. He attended Cornell University, where he received the bachelor of philosophy degree in 1881, and then entered Albany (N. Y.) Medical College, where he graduated in 1883. In 1884 he was appointed director of the pathologic laboratory in the Bureau of Animal Industry of the U. S. Department of Agriculture, Washington, D. C., where for eleven years he investigated infectious diseases of animals. He was also professor of bacteriology at Columbian University, now known as George Washington University, Washington, D. C., from 1886 to 1895, at which time he was called to be director of the pathologic laboratory of the Massachusetts State Board of Health, a position he held for twenty years. During this time he also served as professor of comparative pathology at Harvard University. From 1915 to 1929 he was director of the department of animal pathology at the Rockefeller Institute for Medical Research and since

1901 was a member of the board of directors of the institute. Dr. Smith was a member and past president of the American Association of Pathologists and Bacteriologists and past president of the National Tuberculosis Association; a member of the American Society for Experimental Pathology, the National and American Academies of Arts and Sciences and the Association of American Physicians; honorary member of the Société de pathologie exotique, Paris, France, Royal Academy, Denmark, Reale Istituto, Lombardo, Italy, Swedish Medical Society,

THEOBALD SMITH, M.D.
1859-1934

Medico-Chirurgical Society, Royal College of Physicians, Edinburgh, and the Royal Society of Medicine, London; honorary fellow of the Society of Tropical Medicine and Hygiene, London, and the Pathological Society of Great Britain and Ireland.

Dr. Smith's contributions to medical science have been varied and of far-reaching importance. The research for which he was probably most widely known was his differentiation of the human tubercle bacillus from the bovine tubercle bacillus, a study that has been vastly important through the years of effort for the control of tuberculosis. In the field of anaphylaxis, he and others demonstrated that dead bacteria may produce immunity to disease, a discovery that has been important in the development of vaccines against typhoid fever and some other infectious diseases. He investigated the cause of deaths in experimental laboratory animals used in the standardization of diphtheria antitoxin after having been given a second dose of serum a few weeks after the first dose, which observation has come to be known as the "Theobald Smith phenomenon." Thus he brought to the attention of scientists the existence of hypersensitive conditions. In his research on Texas fever in cattle, he discovered that the disease is due to a protozoon and that it could be carried to cattle in other areas by means of a tick, *Boophilus bovis*. His work on Texas fever proved that insects may be the intermediate agencies in the spread of some infectious diseases and thus he opened the way for the explanation of the causes of transmission of such diseases as yellow fever and African sleeping sickness. Early in his scientific career, he described a bacillus that was associated with cases of hog cholera. He studied the causes of diseases among some of the smaller domestic animals and devised methods for controlling some diseases that formerly eliminated whole flocks. He also experimentally produced scurvy in laboratory animals and thus opened a field of study in human health and disease that has been carried on by many others. Dr. Smith was awarded honorary degrees from a number of universities in this country and abroad and was the recipient of the Mary Kingsley, Kober, Flattery, Trudeau, Sedgwick, the

Holland Society and the Gerhard medals. His scientific work, however, has been even of greater importance than the honors that have been bestowed upon him would indicate.

Edward Baldwin Gleason @ Philadelphia; University of Pennsylvania School of Medicine, Philadelphia, 1878; professor of otology, University of Pennsylvania Graduate School of Medicine; formerly professor of otology, Medico-Chirurgical College of Philadelphia and at his alma mater; member of the American Academy of Ophthalmology and Oto-Laryngology and the American Otological Society; ex-visiting laryngologist to the Philadelphia Hospital; surgeon in charge of the nose, throat and ear department, Northern Dispensary; author of "Diseases of the Nose, Throat and Ear"; aged 80; died, November 30, of cardiorenal disease.

Daniel Joseph Healy, Lexington, Ky.; McGill University Faculty of Medicine, Montreal, Que., Canada, 1896; member of the Kentucky State Medical Association; professor of bacteriology, 1910-1919, and for many years professor of agricultural bacteriology, Kentucky University, and research bacteriologist to the Experimental Station; health officer of Lexington, 1900-1901; pathologist to the Eastern Kentucky Asylum for the Insane, 1897-1899, and the Central Indiana Asylum for the Insane, 1899-1900; superintendent of the Kentucky Institute for Feeble-Minded Children, 1909-1910; aged 61; died, November 24.

John Livingston Crofts, Newport, N. Y.; Albany (N. Y.) Medical College, 1900; member of the Medical Society of the State of New York; past president of the Medical Society of the County of Herkimer; served during the World War; county coroner; health officer of the town and village of Newport and the towns of Norway and Ohio since 1924; school medical inspector of several districts; medical director of the Herkimer County Hospital; aged 56; died suddenly, November 1.

Elam H. Stevenson, Fort Smith, Ark.; Eclectic Medical Institute, Cincinnati, 1879; member of the Arkansas Medical Society; past president of the state board of health; formerly member of the Eclectic Board of Medical Examiners; on the staffs of St. Edward's Mercy Hospital and Sparks Memorial Hospital; aged 78; died, November 20, of angina pectoris and acute dilatation of the heart.

Philip Benedict McLaughlin @ Sioux City, Iowa; Kentucky School of Medicine, Louisville, 1897; past president of the Woodbury County Medical Society and the Sioux Valley Medical Association; served during the World War; fellow of the American College of Surgeons; surgeon to St. Joseph's Mercy Hospital; aged 61; died, November 3, of arteriosclerosis.

Joseph Binder @ Jersey City, N. J.; University and Bellevue Hospital Medical College, 1915; served during the World War; attending obstetrician and chief of the second division at the Margaret Hague Maternity Hospital and visiting obstetrician to the Greenville, Fairmount and Christ hospitals; aged 44; died, November 27, of coronary thrombosis.

David Moulton Gardner, Northampton, Mass.; Boston University School of Medicine, 1900; member of the American Psychiatric Association; veteran of the Spanish-American and World wars; on the staff of the Veterans' Administration Facility; aged 63; died, November 7, of cerebral hemorrhage and tumor of the pituitary gland.

James Franklin Paddleford, Miller, S. D.; Kentucky University Medical Department, Louisville, 1904; member of the South Dakota State Medical Association; served during the World War; since 1919 superintendent of the county board of health; at various times county coroner; aged 65; died, November 18, of myocarditis.

Milton Edward Weaver, Perkasi, Pa.; College of Physicians and Surgeons, Baltimore, 1904; member of the Medical Society of the State of Pennsylvania; aged 53; died, November 14, in the Easton (Pa.) Sanitarium, of pernicious anemia and an injury of the hip received in an automobile accident.

Charles Louis Mattfeldt, Catonsville, Md.; University of Maryland School of Medicine, Baltimore, 1886; member of the Medical and Chirurgical Faculty of Maryland; past president of the county board of health and formerly county health officer aged 67; died, October 27.

Thomas N. Millikin @ Waynesburg, Pa.; Jefferson Medical College of Philadelphia, 1885; past president of the Greene County Medical Society; on the staff of the Greene County Memorial Hospital; aged 75; died suddenly, November 10, of disease of the coronary artery.

John Charles Macgill @ Catonsville, Md.; University of Maryland School of Medicine, Baltimore, 1891; member of the board of directors of the Spring Grove State Hospital;

aged 64; died, November 16, in the Johns Hopkins Hospital, Baltimore, of pneumonia.

Francis Marion Hubbard, Commerce, Ga.; Atlanta Medical College, 1888; member of the Medical Association of Georgia; past president of the Jackson-Barrow Counties Medical Society; aged 86; died, November 9, of pulmonary edema and heart disease.

Charles F. Palmer, Chambersburg, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1878; member of the Medical Society of the State of Pennsylvania; for many years on the staff of the Chambersburg Hospital; aged 87; died, October 29.

William S. Strode, Lewistown, Ill.; Rush Medical College, Chicago, 1884; formerly member of the board of health; Civil War veteran; past president of the school board; aged 86; died, November 5, near Tucson, Ariz., of cerebral hemorrhage.

William Cornelius Callanan, Buffalo; University of Buffalo School of Medicine, 1884; formerly medical school inspector; on the staff of the Buffalo Hospital of the Sisters of Charity; aged 76; died, December 1, of coronary thrombosis.

John Dunn, Richmond, Va.; University of Virginia Department of Medicine, Charlottesville, 1886; member of the Medical Society of Virginia; emeritus professor of otolaryngology, Medical College of Virginia; aged 71; died, November 7.

William T. Bertrand, Coloma, Mich.; Louisville (Ky.) Medical College, 1894; member of the Michigan State Medical Society; formerly village president; aged 76; died, November 9, in the American Legion Hospital, Battle Creek.

Henry Seymour Clark, New York; Jefferson Medical College of Philadelphia, 1883; member of the Medical Society of the State of New York; aged 78; died, November 11, of paralysis agitans and cerebral arteriosclerosis.

Frank Elbert Smith Ⓢ Decatur, Ill.; Chicago College of Medicine and Surgery, 1913; fellow of the American College of Surgeons; chief surgeon to the Wabash Hospital; aged 51; died, November 7, of lethargic encephalitis.

Robert S. Walker, Ottawa Hills, Ohio; Detroit College of Medicine, 1891; member of the American Urological Association; aged 64; died, November 12, in the Mercy Hospital, Toledo, of carcinoma of the lung and liver.

William W. Hoggatt, French Lick, Ind.; Kentucky School of Medicine, Louisville, 1896; member of the Indiana State Medical Association; served during the World War; aged 68; died, November 27, of uremia.

Arthur B. Freeman Ⓢ Rockville, Mo.; University of Louisville (Ky.) School of Medicine, 1886; past president of the Bates County Medical Society; aged 75; died, November 11, in Nevada, of heart disease.

Charles Wellington Clendenan, North Tonawanda, N. Y.; University of Toronto Faculty of Medicine, 1890; member of the Medical Society of the State of New York; aged 70; died, October 30, of heart disease.

Fielden Straughn Dailey, Tunnel Springs, Ala.; Medical College of Alabama, Mobile, 1871; member of the Medical Association of the State of Alabama; Civil War veteran; aged 87; died, October 29.

Clarence Austin Bicking Ⓢ Pittsburgh, Baltimore Medical College, 1913; formerly on the staff of the Presbyterian Hospital and Dixmont (Pa.) Hospital; aged 49; died, November 21, in Chicago, of heart disease.

Singleton Husted, Los Angeles; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1879; aged 80; died, October 25, of bronchopneumonia and chronic nephritis.

George Alvin Hughes, Edwardsburg, Mich.; University of Michigan Medical School, Ann Arbor, 1882; aged 80; died, November 15, in the Elkhart (Ind.) General Hospital, of gangrene of the leg.

Earl Eugene Boyd, Central City, Neb.; Lincoln Medical College of Cotner University, 1906; served during the World War; formerly mayor; aged 61; died, November 5, of cerebral hemorrhage.

Melvin Ticknor Stone Ⓢ Troy, N. H.; Dartmouth Medical School, Hanover, 1880; formerly member of the state legislature and school board; aged 80; died, November 23, of cerebral hemorrhage.

George Michael O'Neil, Cleveland; Cleveland College of Physicians and Surgeons, Medical Department Ohio Wesleyan University, 1906; aged 54; died, November 11, in the Charity Hospital.

Henry Vance Clymer, Fairfield, Calif.; Willamette University Medical Department, Salem, Ore., 1890; member of the California Medical Association; aged 71; died, October 4.

Roscoe C. Duncan, Poole, Ky.; Kentucky University Medical Department, Louisville, 1906; aged 59; died, November 19, in a hospital at Louisville, of heart disease and asthma.

Emmet L. Ashley, Bigspring, Tenn.; Chattanooga Medical College, 1903; aged 60; died, November 18, of injuries received when the automobile in which he was driving overturned.

William Francis Clute Ⓢ Clare, Mich.; Detroit College of Medicine, 1905; aged 53; died, November 12, in the Bay City (Mich.) Samaritan Hospital, of erysipelas.

William H. Harris, Athens, Ga.; Meharry Medical College, Nashville, Tenn., 1893; aged 67; died, November 12, of injuries received in an automobile accident.

Rezin L. Armstrong Jr., Pleasant Hill, La.; University of Louisville (Ky.) School of Medicine, 1879; aged 77; died suddenly, November 4, of myocarditis.

Clara B. Glines Cross Ⓢ Omaha; Bennett Medical College, Chicago, 1913; aged 52; died, September 29, in the Douglas County Hospital, of lobar pneumonia.

William A. Knell, Baltimore; University of Maryland School of Medicine, Baltimore, 1905; aged 50; died, November 14, of carcinoma of the omentum.

Henry Creasey, Detroit; Saginaw (Mich.) Valley Medical College, 1900; aged 66; died, November 13, in the Receiving Hospital, of cerebral hemorrhage.

A. Leo Franklin Ⓢ Cumberland, Md.; University of Maryland School of Medicine, Baltimore, 1902; aged 54; died, November 19, of heart disease.

Frank Powell Dickinson, Fredericksburg, Va.; University College of Medicine, Richmond, 1899; aged 76; died suddenly, October 31, of heart disease.

Edward Philip Day, Boston; Medical School of Maine, Portland, 1898; member of the Massachusetts Medical Society; aged 66; died, October 31.

Nicholas N. Jensen, Orlando, Fla.; St. Louis College of Physicians and Surgeons, 1891; aged 71; died, October 27, of pernicious anemia.

W. L. Gevedon, Grassy Creek, Ky. (licensed in Kentucky in 1894); Civil War veteran; aged 95; died, October 22, of chronic nephritis.

James William Mulick, Elma, Iowa; Rush Medical College, Chicago, 1899; aged 67; died, November 8, of cerebral hemorrhage.

Frank S. Van Kirk, Langeloth, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1895; aged 65; died, October 17.

Lemuel Eugene Thornton, Riceboro, Ga.; Atlanta (Ga.) College of Physicians and Surgeons, 1901; aged 57; died, October 21.

George Miller Gilchrist Ⓢ Groton, N. Y.; Albany (N. Y.) Medical College, 1898; aged 58; died, August 25, of coronary thrombosis.

Aguilas Cheval, St. Hilaire Village, Que., Canada; School of Medicine and Surgery of Montreal, 1886; aged 72; died recently.

Charles Edward Davies, Wishart, Mo.; St. Louis Medical College, 1881; aged 81; died, October 11, of carcinoma of the stomach.

Benjamin H. Mackall, Barnesville, Ohio; Medical College of Ohio, Cincinnati, 1870; aged 90; died, November 10, of senility.

William Henry Smith, Oakland City, Ind.; Kentucky School of Medicine, Louisville, 1893; aged 63; died, November 11.

Nelson J. Hyatt, Orange, Calif.; State University of Iowa College of Medicine, Iowa City, 1881; aged 78; died, September 27.

John H. Wahl, Reading, Pa.; Medical College of Indiana, Indianapolis, 1888; aged 75; died, November 9, of pneumonia.

John Harold French Ⓢ Hartford City, Ind.; Toledo Medical College, 1913; aged 44; died, November 12, of heart disease.

Marc Henry Crocker, Oakland, Calif.; Oakland College of Medicine and Surgery, 1920; aged 37; died, October 20.

John W. Buchanan, Folkston, Ga.; Kentucky School of Medicine, Louisville, 1882; aged 73; died, in November.

Joseph S. Claypool, Pine Village, Ind. (licensed in Indiana in 1897) aged 85; died, November 24, of heart disease.

Bureau of Investigation

R. N. TROTSKY

A Deportable Alien with Many Aliases and a Criminal Record

The story that follows regarding one R. N. Trotsky—if that should be his real name—gives another interesting example of how a persistent and smooth-working impostor can continue to ply his trade in spite of the fact that the man is a deportable alien with a criminal record.

R. N. Trotsky, *alias* Ray Anthony, *alias* Bob Lukan, *alias* Romano Trosky, *alias* Bob Anthony, is a Russian, born in 1894, height 5 feet 8 inches, weight 162 pounds, with a medium dark complexion, blue eyes and black hair. He is said to have deserted the Russian government in 1920 and fled to America without a passport, dodging the federal officers in the meantime.

The man poses as a physician and has claimed to be a graduate of some Russian university. No evidence has ever been submitted to indicate that this man was ever graduated by any reputable medical school anywhere. Certainly he has never been licensed to practice medicine anywhere in the United States, yet he has persistently violated the medical practice acts of various states, has served time in a state prison for abortion, has been charged with forgery, and was sent to Leavenworth for a year and a day for violation of the Dyer Act (transporting stolen motor cars across state lines) and has been guilty of other forms of swindling.

THE GOVERNMENT RECORD

In the record of the Division of Investigation of the United States Department of Justice, Trotsky's number is 169270. A brief but illuminating history of this person is given in a transcript of the record of this branch of the U. S. Department of Justice:

In 1921 he was charged with selling mortgaged property in Minneapolis and put on six months' probation.

In 1923 he was sentenced to forty days in the workhouse at Minneapolis on a bad check charge.

In 1927, under the name Ray Anthony, he was wanted in Minneapolis for murder.

In 1928 he was arrested by the Police Department of Austin, Texas, under the name of "Dr. Bob Lukan" for violation of the Dyer Act. He was held for the federal charge and was sentenced to the United States Penitentiary at Leavenworth under the name Romano Trosky (No. 30353) for a year and a day.

In 1929, under the name of Romano N. Trotzky, the Police Department of San Angelo, Texas, investigated him on suspicion of violating the state medical practice act; he was released. In the same year at El Paso, Texas, still under the name of Dr. Romano Trotzky, he was charged with swindling and was turned over to the United States authorities. Also in 1929, under the name of Romono Trotsky, he was sent to the Minnesota State Prison at Stillwater to serve an indeterminate sentence, maximum four years, for the crime of abortion. He was received at the prison in December, 1929, and was discharged in March, 1931, and taken into custody by the United States Immigration Service for deportation. His full sentence expired Dec. 6, 1932.

In March, 1931, the Chief Patrol Inspector at El Paso, Texas, arrested the man under the name of Romano Trotsky on the charge of an illegal operation. He appears to have been sentenced to fifteen months' imprisonment, but was released at El Paso on his own recognizance pending orders for deportation, and was to report daily to the inspector in charge at El Paso.

In August, 1932, under the name of R. N. Trotzky, he was arrested by the sheriff at Twin Falls, Idaho, on the charge of practicing medicine and surgery without a license. He was sentenced to four months' imprisonment and to pay a fine of \$100.

THE A. M. A. RECORD

So much for the federal record. The first information that is to be found on this man in the files of the Bureau of Investigation of the American Medical Association is in a letter

received in August, 1925, from a lay correspondent who wanted to know whether a man going by the name of Romano Douglas Anthony was a licensed physician. The correspondent stated that this man was practicing medicine at 225 Walker Building, Minneapolis, but that inquiries at the State Board of Medical Examiners of Minnesota and the Department of Registration and Education of Illinois failed to show that he was licensed in either state. We notified our correspondent that no man of this name, so far as the complete records of the American Medical Association showed, was a graduate of any reputable medical school or licensed to practice anywhere in the country.

The next report came in a letter from Dr. W. Albert Cook of Tulsa, Okla., who wrote that a "Dr. Robert Trosky" had applied to him for a position as an assistant, claiming to be a graduate of the University of Petrograd and to have done hospital work in Minneapolis and Albany. The man mysteriously disappeared a few days before Dr. Cook wrote, and was said to have left numerous bad checks in the hands of business men. Dr. Cook was notified that no man of this name was on record as a graduate or a licentiate, and an item was published in the "Oklahoma Medical News" of THE JOURNAL, July 30, 1927.

Later in the same year—in December, 1927—a letter was received from Dr. Howard S. Browne of Ponca City, Okla., asking THE JOURNAL to publish a warning about a man who had gone under various names but always as a doctor—Romano Makorski Lukangok, *alias* Lukan, *alias* McCormick, *alias* Bob Anthony. Dr. Browne described the man as a Russian who had come to Ponca City about three weeks previously, calling himself Dr. Bob Anthony and stating that he was planning to locate in Ponca City. He gave a story of having formerly been with the Ford Motor Company Hospital and the Manhattan Eye and Ear Hospital, and claimed to be a graduate of a Russian medical school. After staying in Ponca City for about three weeks and getting into the graces of a few well-known people, he was reported to have left town between days with a Cadillac touring car that didn't belong to him, and leaving behind him, as the doctor put it, "several hot checks and unpaid bills about the city." THE JOURNAL published a warning again in the "Oklahoma Medical News" in the issue of Dec. 17, 1927.

Publication of this news item in THE JOURNAL brought a letter from Dr. R. H. Graham of Wichita Falls, Texas, stating that he had just read the item and recognized the "Dr. Bob Anthony" as an impostor who had been in Wichita Falls for about three months during the summer of 1927 where he had run about the same course that he had in Ponca City, writing worthless checks, owing bills, and leaving town with a mortgaged car.

After driving this car—a Cadillac—to Louisiana and other points, he was unwise enough to go to Austin, Texas. On Feb. 2, 1928, city detectives R. D. Thorp and Rex Fowler of Austin arrested Trotsky—who was still going under the name "Dr. Bob Lukan"—in possession of the stolen car, and he was charged with violation of the National Motor Vehicle Theft Act. He was held under \$5,000 bond, and on June 13 of that year pleaded guilty and was sentenced to serve one year and a day in the United States Penitentiary at Leavenworth, Kan. It was while he was in Austin that the police department of that city took the photograph that is reproduced with this article.

After getting out of the United States Penitentiary, he was arrested on July 25, 1929, in San Angelo, Texas, but was released. On Sept. 18, 1929, he was again arrested in El Paso, Texas, charged with theft. The charge was *nolle prossed* and he was turned over to the United States authorities. They apparently turned him over to the authorities in Minnesota, where he was wanted on the charge of abortion. He was sentenced, as has already been stated, to the Minnesota State Prison, being discharged in March, 1931, when he was again taken into custody by the United States immigration authorities for deportation.

The next that the Bureau of Investigation of the American Medical Association heard of this man was in August, 1932, from an attorney in Flagstaff, Ariz., who stated that R. N. Trotzky had been charged with murder as the result of the death of a patient following an illegal operation, and that he (the attorney)

had been asked to take the case, but before doing so had wanted to know something of the man's record. The attorney was furnished with such records as the Bureau of Investigation had up to that time. As a result, the attorney declined to represent Trotsky. However, whoever did represent him got an acquittal.

In February, 1933, a letter was received from Dr. D. F. Harbridge, Secretary of the Arizona State Medical Association, enclosing a notice from Dr. J. W. Bazell, Secretary of the Navajo-Apache County Medical Society, relative to Trotsky. The county society reported that the man had attempted to practice medicine in Winslow, having arrived in that city in July, 1931, and representing that he was a graduate of European medical schools, had a license to practice in Arizona, and was a specialist in eye, ear, nose and throat surgery. The local men soon discovered that Trotsky had no license or credentials or diploma, and the county attorney of Navajo County filed a criminal complaint against Trotsky, charging him with practicing medicine without a license. He was tried and convicted. Another complaint charging the same crime was filed against him, and while out on bond pending the hearing on the second charge, he skipped from Winslow to Flagstaff. Dr. Bazell stated further that it was understood that Trotsky at the time that this letter was written (February, 1933) was lecturing from Station KSL at Salt Lake City, Utah, where he was posing as an eye, ear, nose and throat specialist.

The next heard about Trotsky was in a letter from Dr. J. N. Davis, Secretary of the South Side Medical Society, Kimberly,

R. N. Trotsky, alias Bob Anthony, alias Ray Anthony, alias Bob Lukan, alias Romano Trotsky. This man is a deportable alien who has persistently violated the medical practice act of various states, has served time in the Minnesota State Prison for abortion, went to the federal penitentiary at Leavenworth for a year and a day for violation of the Dyer Act, and has been charged with forgery and other forms of swindling.

Idaho, who wrote for any information the Bureau of Investigation might have on a "Dr. R. N. Trotsky," who, Dr. Davis stated, was now located in Twin Falls, Idaho, where he was posing as an eye, ear, nose and throat specialist. Dr. Davis said that Trotsky claimed to be a cousin of Leon Trotsky and also claimed "to have practiced at Leavenworth, Kan." The latter claim indicates that Trotsky has some sense of humor, when one remembers the year and a day that this swindler spent in the United States Penitentiary in that city.

Dr. Davis was sent all the information that the Bureau of Investigation had on Trotsky. The Twin Falls authorities acted and on August 21, 1933, under the name of Robert N. Trotsky, the impostor pleaded guilty to a violation of the medical practice act and was sentenced to serve a four months' term in the county jail and pay a fine of \$100. Judge W. A. Babcock, who sentenced Trotsky, said in open court:

"I am sorry it is impossible under the law dealing with this offense to remove the defendant farther from society because of his past record as a menace to society. Reports from the United States department of justice show that he has been convicted and served time at least twice for other and more serious crimes."

TROTSKY'S LATEST

This brings the Bureau of Investigation's record of Trotsky down to the present. On September 21, this year, the Santa Cruz County Medical Society at Nogales, Ariz., wrote to the Bureau of Investigation for information regarding Trotsky. The society was immediately sent by telegraph and air-mail

such information as was available, and was asked for details regarding Trotsky's activities in Nogales.

Incidentally, it is worth recording at this point that in the fall of 1926 Trotsky turned up at Phoenix, Ariz., under the name of Dr. Lukan. So skillfully did he play his cards there that a local hospital took him on to its staff as a paid intern. He was in Phoenix nearly six months, leaving with a Cadillac car to which he did not have a clear title.

It appears that Trotsky came to Nogales about August 1. Learning that the man was an illegal entrant into this country, as well as an illegal practitioner of medicine, the Santa Cruz County Medical Society, through its president and secretary, confronted Trotsky and the local physician with whom he was associated with these facts on September 10.

On September 14 the county attorney addressed a letter to Trotsky, sending copies thereof to the physician with whom he was associated and to the president of the county medical society, in which Trotsky was told to refrain from practicing medicine until he was properly licensed to do so, and further informing him that by practicing medicine in the office of the physician already referred to, he was jeopardizing that man's license. Trotsky apparently paid no attention to the letter, but continued to practice. On September 21 the county society received a letter from Dr. J. H. Patterson, Secretary of the Arizona State Board, stating that Trotsky did not have an Arizona state license nor had he ever made an application for a license (although Trotsky had declared that such an application had been made). Dr. Patterson further notified the county society that Trotsky had served at least one term in prison, and he advised the society to have the county attorney prosecute Trotsky without delay.

As a result, a complaint was drawn up and a warrant issued for Trotsky's arrest. He was arrested September 21 and released on bond. Since that time he has been arrested twice more on similar charges, and once for disturbing the peace. On the latter charge Trotsky pleaded guilty and was sentenced to serve five days in jail, which he served. On one of the former charges he was found guilty and sentenced to sixty days in jail. A verbal notice of appeal was given and bond was placed at \$300. The court case at Nogales was briefly described in a Tucson paper in part as follows:

"NOGALES, ARIZ., Nov. 5.—(Special).—Dr. R. M. Trotsky of Nogales, a nephew of Leon Trotsky, former Russian Red leader and himself a refugee from the Soviet, was found guilty in a local court of practicing medicine without a license from the state board of medical examiners.

"The prosecution was conducted by Cecil Edwards, a deputy attorney general from Phoenix and three local attorneys, E. R. Thurman, James V. Robins and Nasib Karam. Dr. J. H. Patterson, state secretary of the state board of medical examiners, also aided in the prosecution. Duane Bird represented Trotsky and immediately filed notice of appeal. . . .

"Evidence was introduced by the Santa Cruz Medical society and the attorney general's office at the trial that Trotsky had been convicted of several felonies involving malpractice in other states and Dr. Patterson testified that Trotsky had never applied for a license to the state board at Phoenix. . . .

"Judge Charles E. Hardy sentenced Dr. Trotsky to 60 days in the county jail after finding him guilty of the charges."

Following the trial, and while he was out on bail, Trotsky appears to have staged a somewhat theatrical episode, presumably for the purpose of gaining sympathy. On November 16 he appeared at the home of a man who lived about two miles north of Nogales and asked for aid, saying that he had been shot in the arm. He was said to be suffering from a wound in the fleshy part of the upper left arm, and he was taken to the office of a local physician for treatment. Trotsky's story, according to the local paper, was that he "had been taken for a ride by a pair of strangers." The newspaper report of the case states that powder burns surrounded the bullet holes, showing that the shot had been fired at close range. The same paper—*Nogales International*—stated that Trotsky is said to have declared that he did not know the exact spot where the shooting occurred! The paper added:

"Dr. Trotsky has been in the limelight here considerably recently as a result of having been arrested for practicing medicine without a license and disturbing the peace. He was found guilty of the first charge and pleaded guilty to the latter. On the first charge he was given a 60-day jail sentence and on the latter a 5-day jail sentence."

Thus the case stands. We understand that appeals have been made to Senators Carl Hayden and Henry F. Ashurst and Congresswoman Isabella Greenway to learn whether something cannot be done to expedite the deportation of Trotsky. The man's record is a disgrace.

Undoubtedly the secret of this criminal's ability to get away with crimes from petty swindling to abortion lies in the fact that he is good-looking, makes a good appearance, has brains, and, more and above all, colossal assurance and impudence.

Correspondence

TANNIC ACID TREATMENT OF BURNS

To the Editor:—In *THE JOURNAL*, November 17, page 1556, Dr. J. A. Hagemann refers to a suggestion regarding the use of tannic acid in burns made in 1890. In discussions of the use of tannic acid in the treatment of burns, it is usual to credit its use to a comparatively recent recommendation. An early publication which advocated its use seems to have been overlooked.

In April 1871, Dr. W. H. Searles of Warsaw, Wis., published a short article entitled "Tea-Leaves as an Application to Burns and Scalds." The article appeared in the *Chicago Medical Examiner*, April 1871, page 207. This was the journal edited by Dr. N. S. Davis Sr. As the article is brief, it may be quoted entire:

Some few years since I accidentally found that a poultice of tea-leaves, applied to burns and scalds, afforded immediate relief, and I determined to give it a more extensive trial when opportunity should present, and which soon occurred.

It was in a case of a child 14 months old. Upon examination I found the entire anterior portion of the body, arms and legs blistered and deeply burned from a kettle of hot water which the child had upset upon itself. The case, to say the least, was unfavorable for the success of any remedy.

I prepared a large poultice, softening the leaves with hot water, and, while yet quite warm, applied it upon cotton-wool, over the entire burned surface.

Almost like magic, the sufferings abated, and, without the use of any other anodyne, the child soon fell into a quiet sleep.

In a few hours I removed the application, and reapplied where it was necessary. I found the parts discolored and apparently tanned. The acute sensibility and tenderness had nearly disappeared, and the little patient passed through the second and third stages under far more favorable circumstances (symptoms) than was at first anticipated, making a recovery in about two weeks. Since then, on several occasions, I have had reason to commend tea-leaves, till now I have come to prefer it above all other remedies in the first stage of burns and scalds. I think it must recommend itself to the profession, not only on account of its intrinsic worth, but also by reason of its great convenience, being so readily obtained.

I am not aware that any mention has been made thus far of this article in this connection, and I hope that others will find it as useful in their hands as the writer has.

Dr. W. H. Searles graduated from the Chicago Medical College (later Medical Department of Northwestern University) in 1865. He was one of the first specialists (eye, ear, nose and throat) to practice in Wisconsin. He died in 1914, aged 75 years.

GEORGE H. WEAVER, M.D., Chicago.

PALILALIA IN CONNECTION WITH HABIT SPASM

To the Editor:—Your editorial of December 1 interested me very much. For many years I have occasionally observed palilalia in children at the age of puberty, in boys much more frequently than in girls. The histories always revealed that this condition was preceded by "habit spasm" or tic of several weeks or months duration. The word-repetition is generally explosive in character and offensive in meaning (coprolalia), the expressions quite frequently relating to sex. The cases are usually of long duration and best managed away from home, preferably in a private sanatorium for nerve disorders.

HERMAN B. SHEFFIELD, M.D., New York.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

TUBERCULOSIS IN NURSES

To the Editor:—I am told that it has been the experience at many tuberculosis hospitals that the nurses who at the start of their service at the hospital have negative tuberculin tests are most likely to acquire active tuberculosis. Please give references in the literature. Can you give me the names of any hospitals which have adopted a rule that only nurses with positive tuberculin tests be accepted? Please omit name.

M.D., New York.

ANSWER.—If no differentiation is made in the types of disease developed, the answer must be yes, since the first infection type of tuberculosis is the only possible way that a negative reactor can respond to an initial exposure. The proportion of negative reactors who are exposed and who develop the first infection type of tuberculosis has been cited in numerous references in the literature. There is no available study covering a sufficiently long period to encompass the entire course of the disease which contrasts the outcome of positive and negative reactors on entrance to schools of nursing.

Heimbeck of Oslo (*Med. Klin.* 29:1731 [Dec. 27] 1933) found that approximately 50 per cent of the girls who entered the Ullevål Hospital as probationers reacted negatively to the tuberculin test. Before they graduated, however, 100 per cent reacted positively, thus showing that in line of duty tubercle bacilli had been transmitted to their bodies and had set up tubercle formation. Thus, the first infection type of tuberculosis had been produced in the body of each girl who was previously negative to the tuberculin test. A careful search for the focus revealed it in the lung in some cases, in most of which it had the characteristics of the first infection type of disease and caused no symptoms. In a few, however, a reinfection type of disease, such as pleurisy with effusion, meningitis and pulmonary tuberculosis occurred. In other cases the only manifestation of the first infection type of tuberculosis, aside from the positive tuberculin reaction, was erythema nodosum. In the majority the location of the first infection type of lesion was not determined. Thus, Heimbeck observed these negative reactors as they first became infected with tubercle bacilli and recorded the manifestations of disease, which he was carefully seeking. The group of girls who entered his institution positive to the tuberculin test had already gone through these manifestations in the development of their first infection type of disease before he saw them.

Geer showed that from 65 to 70 per cent of the probationers in the Ancker Hospital in St. Paul had not been contaminated with tubercle bacilli, as evidenced by the negative tuberculin test on entrance, but all reacted positively to the test after having taken a tuberculosis service and before graduation. In approximately 5 per cent of these girls, pleurisy with effusion made its appearance or parenchymal lesions were demonstrated.

Myers, Diehl and Lees (*THE JOURNAL*, June 23, 1934, p. 2086) have found that the incidence of positive tuberculin reactors among probationers in hospitals in Minneapolis varies from approximately 14 to 40 per cent. In those hospitals with special tuberculosis services which the students are required to take, approximately 100 per cent react positively to the test during the senior year. In a few of their cases, the first infection type of lesion has been demonstrated by the x-ray film and in a small percentage pleurisy with effusion, erythema nodosum and other conditions have been present. In the majority of the students who became positive to the tuberculin test, no phase of the examination is sufficiently refined to detect the exact location of the lesion to date. In other schools, where tuberculosis services did not exist but where the occasional case of tuberculosis was admitted, they have shown that there is a definite increase in the incidence of positive reactors among the student nurses before graduation but that it is by no means as marked as in the schools with tuberculosis services. They contrast the results in schools of nursing with those in a school of education, where they found approximately 23 per cent of the entering students reacting positively to the tuberculin test, whereas after four years in school there had been an increase of only 4 per cent in the positive reactors.

Shipman and Davis (*Am. Rev. Tuberc.* 27:474 [May] 1933), after nearly a decade of observations on tuberculosis among students of nursing, found that between 6 and 7 per cent of

the students in the University of California Hospital developed clinical tuberculosis during training, while an additional 4 per cent had developed the disease between graduation and the time the study was reported. They found that the majority of nurses who reacted negatively to the tuberculin test as probationers remained negative throughout their training. This they believed was due to the fact that there is very little tuberculosis among the patients in the University of California Hospital.

Ross (*Canad. M. A. J.* 22:347 [March] 1930) has shown that during their training or within one year after graduation about 6 per cent of the nurses in Manitoba fall ill with tuberculosis. This, he found, was far beyond the proportion in which women of the province in general, or any other class of women, fall ill from tuberculosis.

Jones (*Tubercle* 15:59 [Nov.] 1933) made a study of tuberculosis among nurses in a New Zealand hospital. He found that approximately 3 per cent of the girls in training fall ill from tuberculosis each year. He then compared this incidence with that of girls from teacher training colleges who did not come in contact with tuberculous patients. Among them he found but little tuberculosis. He concluded that girls of this age (19 to 25) remain in excellent health while they are subjected only to healthful conditions but that when they are exposed to tuberculous patients all become positive reactors to tuberculin and 3 per cent each year develop clinical tuberculosis.

Ferguson (Special Bulletin of the Saskatchewan Anti-Tuberculosis League, 1934) has shown that in Saskatchewan the incidence of tuberculosis among nurses in training is twelve times the incidence of the disease in the general population and is eight times the incidence found among normal school students, mostly females and of approximately the same age.

In interpreting the results of various authors who have studied tuberculosis among nurses, one must realize that two types of tuberculosis develop in the human body, the first infection and the reinfection type. The former begins to develop on tissues that are not allergic to tuberculin. The natural defense mechanism of the body brings it under control and has it so encapsulated before allergy can be detected that it does little or no harm in most cases. It is so benign that most persons who have it do not know when it developed. This is the type of tuberculosis that formerly was prevalent among children; but through antituberculosis measures many children now escape it and reach young adult life free from contamination with tubercle bacilli. If they later come in contact with tubercle bacilli, as many students of nursing do, and are not adequately protected against exposure to patients suffering from tuberculosis, they take tubercle bacilli into their bodies. These bacilli find lodgment on tissues that are not allergic and there the tissues react as to a foreign body, in short, the reaction is not specific, and the result is not different than it would have been had their first infection occurred in childhood. In a fair percentage of these cases whether in infancy, childhood or young adult life soon after infection occurs and when allergy is high, erythema nodosum develops. While not all cases of erythema nodosum are due to tuberculosis, careful observers are of the opinion that it is often an allergic manifestation and should always lead one to seek at least the first infection type of tuberculosis. In the majority of these cases there is no external manifestation aside from the positive tuberculin reaction.

In the case of the reinfection type of tuberculosis, the story is quite different. Here tubercle bacilli find lodgment on allergic tissues and a specific reaction follows. This consists of acute inflammation, and if the bacilli are not brought under control in a short time there is necrosis of the tissue as well as stimulation of fixed tissue cells, resulting in fibrosis. This is what is designated "clinical tuberculosis." It is the type that results in most of the illness and death from tuberculosis in the human family. Obviously, it can develop only in the bodies of persons whose tissues have previously become allergic to tuberculin through the presence of the first infection type of tuberculosis. This type of disease may develop soon after the first infection type renders the tissues allergic or at any subsequent time in life, depending on whether tubercle bacilli are taken into the body from outside sources or whether tubercle bacilli are set free from the foci of first infection already present. In a small number of nurses who become infected for the first time, bacilli are carried to the visceral pleura soon after the first infection occurs, and there on allergic tissue they produce pleurisy with effusion. Likewise from a first infection focus located in or near the central nervous system tubercle bacilli are carried into the ventricles of the brain or directly into the subarachnoid space and on this allergic tissue

they produce diffuse tuberculous meningitis. Again the regional lymph nodes, which drain the first infection focus and become a part of the picture of the first infection type of disease, may rupture into a blood vessel and miliary disease results. And so on with numerous other possibilities, once bacilli are lodged in the body. It is possible that the danger of rupture of capsules of primary foci and the rupture of regional lymph nodes involved with tuberculosis is greater soon after the lesions have developed than in subsequent years, since in infancy and early childhood, in places where large numbers of infants are contaminated, tuberculous meningitis and miliary tuberculosis are prevalent and in recently infected students of nursing, pleurisy with effusion is quite common. However, Sweany on the basis of pathologic examinations (*Am. Rev. Tuberc.* 27:559 [June] 1933) has suggested that nature may defeat her purpose in that she first encapsulates tubercle bacilli and in subsequent years resorbs the capsule, thus setting free tubercle bacilli. Therefore there is both an immediate and a remote danger from the first infection type of disease. Moreover, at all times there is the danger of tubercle bacilli from exogenous sources entering the body and finding lodgment on allergic tissues.

Thus, a large percentage of the cases of tuberculosis reported among students of nursing previously negative to the tuberculin test are only those of the first infection type of disease. In previous times they would not have been known to exist, but now with the tuberculin test and other phases of examination they are detected when no symptoms or physical signs are present. Even those who developed erythema nodosum probably as a result of a high degree of allergy would not have been diagnosed tuberculous, because it is only recently that the close association between this condition and the first infection type of tuberculosis has been generally recognized. A few of these students after developing the first infection type of disease and becoming allergic have developed chronic pulmonary tuberculosis, pleurisy with effusion, tuberculous meningitis, miliary tuberculosis, and other forms of the reinfection type of disease, just as one would expect. At the same time, wherever observations have been made among those who entered the institutions positive to the tuberculin test some of these have developed the reinfection clinical forms of the disease.

Unfortunately, after the first infection type of tuberculosis produces allergy there is no way of determining how much contamination enters the body from exogenous sources. It seems reasonable to believe, however, that if all the uncontaminated students become infected during their training, those who are already contaminated when they enter are reinfected. It is a well established fact that tubercle bacilli, whether from endogenous or exogenous sources, are rather quickly fixed in the tissues, where they lodge by inflammation or otherwise. Unlike many pathogenic micro-organisms, they are not destroyed but survive over long periods and often eventually produce clinical tuberculosis. Thus, a period of years may intervene between the reinfection and the development of illness, a period that is not covered by the duration of the course in nursing. Therefore, bacilli sown while in training may result in serious disease years after students have graduated. In fact, Shipman and Davis have found that most of the nurses who developed clinical tuberculosis during training were positive reactors on entrance to the school.

For any hospital to adopt the policy of admitting to its school of nursing only girls with positive tuberculin reactions, either consciously or unconsciously, would be to avoid the issue. Obviously, there would be no way to determine how much contamination that institution transmitted to its students. It would not be in a good position to solve its own problems.

No hospital is on record as having adopted the policy of admitting to its school of nursing only girls with positive tuberculin reactions. Moreover, if the tuberculosis control program continues, such a hospital would soon find itself without student nurses, as the incidence of positive reactors, already low, is definitely decreasing among girls of the student nurse age. Since there is no possible way of securing a tuberculosis-proof nurse, the other alternative of providing as nearly as possible a bacillus-free environment for the nurse must be accepted. The negative reactor comes to the hospital without any exposure to tuberculosis. She must go through the first infection stage of the disease after exposure before the development of clinical tuberculosis, while her positive reactor classmate has only one possible step left, that of the development of the reinfection and clinical type.

SUSPECTED CARDIOVASCULAR SYPHILIS

To the Editor—A man, aged 56, consulted me for loss of weight, tiredness and fatigue. He weighed 140 pounds (63.5 Kg.), from 172 pounds (78 Kg.) three years ago. He gave a history of syphilis at the age of 20, with oral treatment for five years, presumably iodide and mercury. He also had gonorrhea. Physical examination is entirely negative except for an apical systolic murmur with intermittent drop beats and a murmur at the aortic area. The blood pressure is 165 systolic, 90 diastolic. The prostate is moderately enlarged. The urine is normal. There is no apparent sign of central nervous system involvement. He has been married, divorced, and has one child. I should like to know whether or not to begin treatment. He seems to have lived fairly successfully with his syphilis for thirty five years, which apparently involves only the cardiovascular system. If treatment is indicated, what is the best course? What is the probable infectiousness of the man? Please omit name.

M D, California.

ANSWER—From the information supplied, it is quite impossible to make the diagnosis of cardiovascular syphilis or, indeed, to be sure that the patient has syphilis. Serologic observations in the blood and spinal fluid are not supplied. An apical systolic murmur is not characteristic of cardiovascular syphilis except so far as it may be due either to relative mitral insufficiency or to the transmittal of an aortic systolic murmur, nor are ventricular extrasystoles more frequent in cardiovascular syphilis than in any other type of heart disease. The timing of the aortic murmur in this patient, that is, whether systolic or diastolic, is not stated, nor are details given which might permit the differentiation between arteriosclerotic and syphilitic aortic regurgitation, if the latter valvular defect is actually present. Before treatment is undertaken this patient should have a blood Wassermann test checked by flocculation tests, an examination of the spinal fluid, including cell count, protein estimation, quantitatively titered Wassermann test and colloidal gold, mastic or benzon tests, carried out in a reliable laboratory, and a teleroentgenographic and fluoroscopic examination of the cardiovascular stripe, to measure the aortic width and to rule out the possible presence of an aneurysm.

The blood Wassermann reaction is positive in from 95 to 98 per cent of all patients with untreated cardiovascular syphilis.

If further study of the case indicates that cardiovascular syphilis is the correct diagnosis, the patient should be treated. His treatment should be carried out in accordance with the principles and drugs given in chapter 21 of the monograph "The Modern Treatment of Syphilis," by Joseph Earle Moore, or in chapter 20 of the second edition of "Modern Clinical Syphilology," by Stokes.

This patient is not infectious in any of the ordinary contacts of life, the only possibility of infectiousness (and this is remote) lying in the transmission of the disease by seminal infection.

HYPERTHYROIDISM IN PREGNANCY

To the Editor—B G., aged 24, became pregnant. She was a primipara with no previous pregnancies or abortions. The pregnancy continued normally until the eighth month, when an attack of tachycardia developed. The tachycardia apparently was relieved by colonic flushing and the patient again appeared normal as to bowel movements, blood pressure and urinalysis. Two weeks later there was a rise in blood pressure from 118/60 to 150/72, and a four plus albuminuria. The pulse at this time averaged 90 per minute. A gain of 45 pounds (20 Kg.) had been accomplished during pregnancy. Preeclamptic treatment had been instituted without results. Therefore, after consultation it was decided that a cesarean section be performed, and a healthy male child weighing 8 pounds (3,628 Gm.) was delivered. Following delivery the mother's condition seemed normal except for a fever, which persists and varies from 98.8 to 102.6 F. accompanied by a corresponding tachycardia. After numerous careful physical examinations, I have been unable to elicit anything except a faint mitral blow. The pelvis is normal. The baby is 4 weeks old. Treatment at present consists of one tablet of digifoline every four hours, alcohol sponge baths, a balanced nutritious diet and rest in bed. Any suggestions as to treatment or diagnosis will be appreciated. Please omit name.

M D, Chicago.

ANSWER—Most of the symptoms in this case are highly suggestive of hyperthyroidism. When tachycardia develops during pregnancy, especially if it is associated with an elevation of the blood pressure and other symptoms, an aberration in thyroid function should be considered. Usually these symptoms can be relieved by the administration of compound solution of iodine, five drops three times a day for one week, repeated for another week after an interval of seven days. Should there be a recurrence of the symptoms, the solution should again be prescribed. The pronounced albuminuria and the excessive gain in weight are indications of toxemia but in many if not most cases of toxemia there is an associated disturbance in the function of the thyroid gland. The high fever is most likely not due to the thyroid unless there is an acute thyroiditis, but this condition would present manifest symptoms. At least one reading of the basal metabolic rate should be taken immediately. If the rate is high, appropriate treatment

should be instituted. If the mitral blow is present now and was not present during pregnancy, this fact and persistent fever should make one think of an endocarditis. Some of the symptoms, such as albuminuria, fluid retention and elevation of blood pressure, may be due to an acute nephritis. Therefore the urine should be studied microscopically.

VAGINAL BLEEDING IN NEW BORN

To the Editor—One is not apt to be too keenly interested in certain conditions until it strikes home. Heretofore I have paid no attention to vaginal bleeding in the new born. I consulted several pediatricians, who gave congruous advice, viz., to ascertain the bleeding and coagulating times and unhesitatingly to administer subcutaneously or intramuscularly 20 cc of parental whole blood. This led to further inquiry among nurses in charge of maternity wards and those of many years' experience as well as mothers. From them I learned that the bleeding starts usually on the second day, lasting from three to eight days. The amount is from a stain to a streak or a clot or several clots on the diaper. It is dark and usually mixed with mucus. The nurses say that the baby is menstruating and do not call the attention of the physician to it. There were no other abnormal signs in the cases recalled by the nurses. In the recent four cases that I had, traumatism was not a factor. The deliveries were easy, occurring in a secundipara, two tertiparas and a quadripara. There was no history of bleeders. Two of these four were consanguineous marriages (first cousins). Please discuss etiology and also when treatment is indicated. Kindly omit name.

M D, New York.

ANSWER—The type of bleeding from the vagina described can be demonstrated to arise from the uterus by vaginal examination with an ear speculum. The character of the discharge is rarely free bleeding but rather a more or less intimate admixture with mucus. It usually manifests itself on the sixth or seventh day, occasionally the fourth or fifth, and ordinarily lasts one or two days, rarely over three or four. The uterus in these cases undergoes hyperemia and subepithelial hemorrhages similar to the condition preceding usual menstruation. The ovaries show no sign of function. Within three weeks the uterine changes undergo regression and the organ becomes smaller. A distinction should be made between this occurrence and "precocious menstruation," which occurs later but reappears periodically. The bleeding in new-born infants is due to some type of hormone. It may be present in the pregnant woman's circulation, spilling over to the infant in adequate doses, or it may arise from the placenta, according to Halban. The appearance of "witch's milk" in the new-born also testifies to the presence of such hormones. More striking evidence is furnished by a phenomenon similar to the uterine changes in the female which occurs in the prostate of the male. Here, too, hyperemia, hemorrhage and secretion have been demonstrated, and transitory hematuria sometimes appears as a counterpart to the vaginal bleeding of the girls. Still further evidence of the hormone etiology is the frequency of edema of the penis and scrotum and enlargement of the testicle of the new born male when trauma and other conditions can be excluded. The condition itself requires no treatment, but other causes of vaginal bleeding must be excluded that may require attention, such as the hemorrhagic diathesis, sepsis, trauma and malignant conditions.

INFLAMMATION OF PROSTATE AFTER GONORRHEA

To the Editor—A man, aged 26, contracted gonorrhea about three years ago. The first day of discharge he visited a physician, who treated him by advising the use of a syringe daily of silver nitrate, together with methenamine internally. He received no massages or soundings. After seven weeks he omitted all treatment, because the discharge had disappeared. For six months he used oil of sandal, until pain in the perineum appeared, which, although not constant, troubled him. He also states that with each bowel movement there was a marked discharge of a thick mucoid substance from the penis. He visited another physician at this time, who said that the smear showed no gonococci. For seven weeks massage was done twice weekly and a sound passed once weekly. The discharge lessened, as well as the severity of the pain. After three months without treatment he began to have pain in the perineum, and a chronic discharge following each bowel movement. At present he is receiving massage twice weekly, with a silver nitrate injection, and washing out of the bladder once weekly, but the pain still continues. I would be thankful for further advice in this case.

M D, Rhode Island.

ANSWER—Any treatment outlined for this patient should depend on further studies, but from the available history certain diagnostic possibilities present themselves. The persistence of perineal pain is strongly suggestive of infection involving the prostate and seminal vesicles, and it is only by examination of the prostatovesicular fluids on repeated occasions that this may be determined. Calibration of the urethral canal should likewise be carried out to make known urethral strictures, should they exist. Should these studies reveal no abnormality, one's attention is drawn to a possible presence of a

verumontanitis, which is occasionally encountered and may give rise to obscure but exceedingly annoying pain.

Treatment if directed toward an existing prostatovesiculitis should consist of weekly massage followed by the through and through irrigation of 1:4,000 potassium permanganate solution or 5 per cent silvol solution, depending on the degree of infection as evidenced by the character of the urine. Progressive dilation of the urethra followed by one of the foregoing solutions is required should a stricture be demonstrated. If reasonable evidence of a verumontanitis exists, gratifying results frequently follow the use of massage and one of the dehydrating agents, such as 5 per cent sulphonated bitumen in glycerin, which should be instilled into the posterior urethra by means of a Guyon or an ordinary small rubber catheter at weekly intervals.

The importance of a urethral discharge appearing with each bowel movement should not be overestimated. The mechanical factors operating during defecation may readily result in the expression of normal prostatic fluid if the fecal material is bulky and hard. It is well to note in this case that with treatment so prolonged and varied a neurotic element may enter into the patient's subjective symptoms.

DELAYED POST-TONSILLECTOMY HEMORRHAGE

To the Editor:—Can you tell me just what takes place in delayed post-tonsillectomy bleeding? In my experience this has been a very annoying complication and I have been at a loss to determine why it should occur. I encounter it most frequently in children that are normal in every respect, that have a normal bleeding and clotting time, a very slight bleeding at the time of the operation, and without evidence of any post-operative infection. This bleeding usually starts about the seventh post-operative day and is so slight that it is recognized only when the patient vomits dark red blood. A bluish dark clot is found filling one tonsil fossa, and until this is removed the bleeding recurs at intervals within a few hours to one or two days. Wiping out the clot stops the bleeding and I have never found the use of any hemostatic to be of any value. I have never felt that infection played any part in the majority of these accidents. Is it probable that there is some enzyme in the saliva that plays some part in this delayed bleeding? Rarely do these patients bleed extensively at the time of the operation and I have never seen a fatal accident. In my past experiences it has been the most disturbing part of a tonsillectomy, as I have found it impossible to predict or prevent. I would appreciate any information that you might have on this subject.

M.D., Kansas City.

ANSWER:—Even though no definite signs of infection of the tonsil fossa can be seen, the bleeding that occurs from four to ten days after operation is usually due to sloughing of a small portion of the wound and the opening thereby of a small vessel. The whole condition probably results from infection of the wound by secretions in the mouth or throat. Trauma in the way of eating substances that have sharp edges, such as nuts, or undue exercise, may cause bleeding.

We do not know of any data regarding the action of any enzyme in the saliva itself that causes changes in the wound surface resulting in bleeding. It is possible that at times the use of catgut for ligatures may cause this delayed bleeding if the catgut is not promptly absorbed. When plain, fine catgut is used, the ligature usually opens within twenty-four to thirty-six hours and the catgut disappears. If, by chance, chromic catgut is used, the absorption will be greatly delayed and the ligature may act as a foreign body, producing inflammatory reaction in the tissue.

It is quite true that the delayed bleeding often occurs in cases in which the tonsils are smoothly removed and at the time of operation there is only slight bleeding. We are unaware of any procedure that can be used at the time of operation that will prevent late postoperative bleeding.

HAZARDS OF ALUM AND BORAX INDUSTRY

To the Editor:—Can you give me any information or tell me where I could find any on occupational hazards of workers in alum and borax plants? Is there any evidence especially from postmortem examinations that long exposure to dust from such plants is apt to cause bodily changes such as pulmonary fibrosis or polycythemia? Please omit name.

M.D., California.

ANSWER:—Belief that borax and alum (aluminum and potassium sulphate) possess industrial toxicity is chiefly predicated on knowledge of the action of these substances after accidental ingestion. During the last ten years a number of fatalities have arisen from intake of these chemicals mistaken for saline cathartics. The cases from borax outnumber those from alum. Borax produces a prompt salivation, vomiting, abdominal colic, diarrhea, delirium, cyanosis, and edema of the respiratory tract, culminating in early collapse. If the amount ingested lies below that producing prompt death, there may arise, in addition to some of the foregoing, hematuria, albuminuria, nephritis, cystitis and so on. The toxic action of alum after ingestion centers

about gastro-intestinal inflammation. For years the use of alum-containing baking powders has been held up to criticism.

In industry, alum may be accepted as a source of dermatitis, particularly when the exposure provided is to alum solutions. The dermatitis produced is characterized by maceration of the skin. The dust from both borax and alum inhaled in large amounts over long periods will produce a low grade fibrosis connected with a bronchiolitis. The roentgenogram will not reveal a characteristic picture such as is associated with silicosis but will resemble the hazy films sometimes found in workers long exposed to mineral acid vapors or alkali dusts. These statements are not based on actual observations but on the current concept that all dusts are in some measure harmful to the lung tissues and in time will stimulate the formation of more fibrosis than normal.

BURNING OF TONGUE AND CANKER SORES

To the Editor:—A widow, aged 45, American, complains of burning and painful tongue of about four weeks' duration. Original examination disclosed an irregular grayish area about 15 by 5 mm. in size on each side of the tongue at about the area of the molars. Although there is no infiltration present, I have diagnosed these to be leukoplakia. In addition, the patient complains of some burning arising from several small fissures on the dorsum of the tongue near the tip. Physical examination is essentially negative, with the exception of a moderately acid reaction in the mouth and a faint albuminuria. The patient has been referred to a dentist, who removed any dental irritations present. There has been some subjective improvement on alkaline therapy, which changed the salivary reaction to the alkaline side and the use of one-half strength alkaline aromatic solution twice daily. In the past few days I have noted a new feature; namely, a small ulcer about 2 to 3 mm. in diameter located just proximal to the left leukoplakia. May I have your suggestions as to diagnosis and treatment. Kindly omit name.

M.D., California.

ANSWER:—It is assumed, though not specifically stated, that there is no infiltration in connection with the small fissure mentioned. If this is true, the condition is probably a mild form of scrotal tongue, a congenital malformation. Burning sensations in connection with such fissures are most often neurotic. The small ulcer, if it has no infiltration of its border, is most probably a canker sore and should clear up after cauterization with a crystal of silver nitrate. Canker sores occur frequently from slight digestive disorders, sometimes apparently as a sensitization to some food. Some consider them a form of herpes simplex; but that has not been proved.

The treatment mentioned is excellent. Great care should be taken not to frighten the patient by discussing the possibility of cancer, unless it is necessary in order to obtain her cooperation. Many patients, particularly women, with this symptom complex are cancer phobes, and their fears should be allayed as much as possible, the physician assuming the responsibility, by frequent examinations, of detecting any tendency to infiltration at its incipience, and giving prompt and energetic treatment.

TABETIC PAINS AFTER TREATMENT

To the Editor:—I am treating a case of syphilis. After each intravenous injection of arsenic the patient is all right for about five hours. He then gets a slight headache and within an hour is suffering from such excruciating pain in the right half of the face and forehead that it is necessary to give him morphine. This state of affairs usually lasts from thirty-six to forty-eight hours, during which time he will have had several hypodermic injections. Thereafter he is entirely comfortable until he is given another intravenous injection. On one occasion I gave him an intramuscular preparation of arsenic and that was followed by the worst attack of pain he had ever had. The amount of arsenic given does not seem to bear any relationship to the degree of pain. Salicylates, diathermy, and so on, are useless. He is not a morphine addict. Can you suggest any treatment whereby the patient can be adequately treated for his disease without having to go through such agony? He is also being given a bismuth compound intramuscularly, but this does not inconvenience him at all. Please omit name and address.

M.D., Ontario.

ANSWER:—Exacerbations of tabetic pains after intravenous or intramuscular injection of arsphenamine or its derivatives is a fact well known to all syphilologists. It is not known, however, whether this is due to direct toxic action on damaged nerve centers, circulatory disturbances in the central nervous system, or a toxic action on the liver, causing it to set free a histamine-like substance.

Tabetic pains may be temporarily increased by fever therapy, intraspinal therapy or acute or chronic infections as well as by arsphenamine. Tryparsamide does not cause such reactions. Moore mentions pain in the teeth and gums as part of a nitritoid crisis (Moore, J. E.: *Modern Treatment of Syphilis*, Springfield, Ill., and Baltimore, Charles C. Thomas, 1933, p. 76).

The patient should be studied further to discover any central nervous involvement, and further treatment should be governed by the results. Morphine is tabu. It does more harm than the

benefit that has been derived from the injection of the arsenical. No more arsphenamine should be given until the patient has been given a course of bismuth compounds. Then a small dose of neoarsphenamine may be tried and further injections given if it causes no disturbance.

TRAUMA TO SKULL AND OPHTHALMIC INFLAMMATION

To the Editor:—A man, aged 21, received a blow on the head by a falling jar, producing a temporal laceration. Twenty-four hours later an inflammation of the eye appeared on the same side, which in three days developed into an iridocyclitis. Roentgenograms were negative. A woman, aged 40, received an injury from a falling sign, which produced a laceration in the temporal region, and twenty-four hours later an inflammation of the eye appeared on the same side. Within a few days this developed into an acute iridocyclitis. Roentgenograms were negative. In neither of these cases was the patient unconscious, and all other physical observations were negative. Please advise if in your opinion there could be any causal relation, from a pathologic and medical standpoint. Please omit name.

M.D., California.

ANSWER.—It is difficult to understand what connection there could be with such trauma as described and an iritis unless there was some trauma, even a blunt one, to the eyeball. A blunt injury might have caused a thrombosis of the long posterior ciliary artery (producing clinically Wagemann's classic experiment on a rabbit's eye). The local hyperemia may have been caused from a blow and any bacteria that may have been in the blood stream may have appeared in the eye in greater numbers and lighted up an infection, which took the form of an iritis. Fracture of the bones of the orbit may have produced an injury leading to this condition. A detachment of the retina must be ruled out, as this condition is frequently followed by iritis, though rarely in less than six weeks. An injury to a branch of the fifth nerve, which supplies the cornea, might produce a keratitis or an ulcer, and an iritis may be secondary to that. The history does not mention any corneal involvement.

CARE OF TEETH IN PREGNANCY

To the Editor:—Will you please give me the latest theories regarding the protection of the mother's teeth during pregnancy: (1) any drug to be given; (2) any special articles in diet?

LEROY L. BELT, M.D., Marblehead, Ohio.

ANSWER.—It is important for every expectant mother to have her teeth examined and cleaned at least twice during her pregnancy. If the dentist finds defects that he can remedy, it is perfectly safe for him to correct the abnormalities. But he should not do more than is absolutely necessary. He may fill (using temporary fillings), clean and pull teeth but not make gold fillings, inlays or bridge work, which require a long time and which cause a good deal of discomfort.

In many pregnant women the teeth decay and loosen and in practically all of these women this abnormal process may be corrected by eating an abundance of calcium (chiefly in the form of milk), phosphorus (chiefly in the form of eggs), cod liver oil, halibut liver oil, viosterol, fresh fruits, vegetables, butter and whole grain cereals. These foods will help not only the mother's teeth but also the teeth of the unborn child. Likewise an abundance of sunshine is essential in order to enable the body to utilize the calcium and phosphorus that are eaten. The teeth should, of course, be carefully brushed at least twice a day and dental floss used to remove particles of food lodged between the teeth. If the gums have a tendency to bleed, they should be vigorously massaged with the fingers two or three times a day.

Many obstetricians prescribe as a routine the daily use of halibut liver oil with viosterol during the entire period of pregnancy. In addition, pregnant women are advised to drink a quart of milk a day in order to be certain that they secure enough calcium.

INJECTION TREATMENT OF HYDROCELE

To the Editor:—In *THE JOURNAL*, July 21, is an abstract on treatment of hydrocele from an article in the *Presse médicale*. Are the eighteen cases treated with Vendel's solution (double chlorhydrilactate of quinine and urea in glycerin) the first cases reported? If not, what further can you say about this treatment, favorable and unfavorable? Where can Vendel's solution (preferably ready to inject) be obtained? If this solution cannot be obtained, where can double chlorhydrilactate of quinine and urea be obtained? Please omit name.

M.D., New York.

ANSWER.—The injection treatment of hydrocele is by no means new. In the July 28 issue of *THE JOURNAL* a brief discussion of this topic can be found in *Queries and Minor Notes*. In the article quoted by the correspondent, the sclerosing substance is not 10 per cent quinine and ethyl carbamate as customarily used but 25 per cent quinine dihydrochlorlactate

in glycerin. The author does not offer any proof that this solution is superior to the aqueous solution of quinine, but it is possible that the dehydrating action of glycerin may add to the destructive effect on the lining of the sac and also retard absorption from the site of injection.

Attention must be called to the fact that 6 cc. of a 25 per cent solution of quinine, used by the author, represent 1.5 Gm. of quinine, which may produce toxic symptoms. The solution is not on the market in this country but can undoubtedly be procured through drug companies that import French products. As other sclerosing products, such as 5 per cent sodium morrhuate, are easily available and are nontoxic, the effort expended in procuring this solution would hardly be worth while. The best treatment of a hydrocele, except in special instances of debility or refusal of operation, is still surgical.

SYPHILIS IN A CHILD

To the Editor:—At the age of 5 months a child developed a rash. Wassermann tests on the entire family revealed positives in the mother and the child (the only one). The father was persistently negative even after several provocative examinations. Treatment of the child consisted of biweekly injections (intramuscular) for five months. The preparations used are unknown to me. The rash is gone and the child appears well. No repeated Wassermann test was done. My questions are these: If early congenital syphilis is to be treated like early acquired syphilis (Beckman), was this treatment, despite the apparent well being of the child, sufficient? Does the criterion of a minimum of one and one-half years of adequate treatment (Stokes, Cole, Moore, O'Leary, Wile, Parran, Vonderlehr and Usilton, *THE JOURNAL*, April 21) hold good here? In view of the undoubted difficulty of intravenous medication in an 11 months old child, would you suggest alternating courses of sulpharsphenamine (which can be given intramuscularly) and a bismuth preparation? Are there any other suggestions you could make concerning the management of this case? I am assuming that the mother, who received five months of biweekly intravenous and intramuscular treatments, was insufficiently treated.

M.D., New York.

ANSWER.—It is not clear from the inquiry whether the child in question is still serologically positive on the blood or not. This information in general is essential to a decision as to treatment. It is not intended that the treatment standard described in the paper by Stokes and his collaborators in *THE JOURNAL*, April 21, is to be applied arbitrarily to infants who develop eruptive manifestations of syphilis. Intramuscular medication with alternating courses of sulpharsphenamine and a bismuth compound would be satisfactory in a case of this sort, and the treatment should be carried through at least eighteen months. The reason for permitting the use of sulpharsphenamine here is the superior tolerance of the infant and young child for this preparation, which in general is not to be commended for adults. The serologic controls and observation through a period of many years apply to this case, and it should be emphasized that a spinal fluid examination with all four tests on which a diagnosis of neurosyphilis may depend should be performed at an early date. Juvenile dementia paralytica, if recognized by serologic criteria before degenerative changes have taken place, is apparently much more responsive to treatment by modern methods than has been generally thought.

PERSISTENT URETHRAL DISCHARGE AFTER GONORRHEA

To the Editor:—A white man, aged 32, contracted gonorrhea in 1928. He has been treated by several doctors since then, quite regularly. He received a fairly intensive course of treatment, consisting of irrigations, internal antiseptics, prostatic massage, sounds, vaccines and rest. His chief complaint is a persistent slight penile discharge, with passage of shreds in the urine. The patient, physically, is in good health. Smears fail to show gonococci but do show numerous leukocytes and gram-negative cocci, presumably staphylococci. The prostate is normal in size and not boggy or tender. The first glass of urine shows shreds, while the second glass is clear. A 26 F. catheter passes without difficulty. The Wassermann reaction is negative. Naturally, after six years of treatment, the patient is quite disgusted and I am writing to inquire as to any suggestions for further treatment you might make. Kindly omit name.

M.D., Pennsylvania.

ANSWER.—The persistence of urethral discharge in this patient may be due to several things. First, it is possible that the patient has a congenital stricture of the external urethral orifice and that this interferes with drainage, although a No. 26 French catheter passes without difficulty. Second, he may have granulations in the anterior urethra, which can be demonstrated readily with a diagnostic bougie.

If either of these conditions is present, the patient should have a meatotomy and thereafter sounds should be passed, beginning with a No. 26 and increasing one number a week.

It is possible that the discharge is due to the presence of infected glands, wherefore a urethroscopic examination is in order. If infected glands are found, they should be destroyed

through the endoscope with a high frequency current. If the entire anterior urethra is normal, one must look for persistent infection in the prostate gland or seminal vesicles or both. This can best be determined by massage of the prostate and vesicles and examination of the expressed fluid.

OPTIC ATROPHY IN SYPHILIS

To the Editor—I am treating a patient who has neurosyphilis and who has been through a period of almost complete loss of mentality. At present he has gained weight and strength under antisyphilitic treatment, which treatment now consists of hismith sodium iodide (intravenously) and liver extract. Optic atrophy with gradual loss of vision has developed. Is there any form of treatment that will in any way hold in check this form of optic degeneration? An ophthalmologist states that there is almost total loss of vision in the right eye, with about 50 per cent loss in the left eye.

GEORGE T. COLEMAN, M.D., Marshall, Texas

ANSWER—In the majority of cases the atrophy, such as here described, progresses to complete blindness despite therapeutic measures. In a few instances the course of the atrophy can be arrested, temporarily at least, by febrile therapy. Malarial inoculations have been used in some of these cases with satisfactory results reported, in other cases, shock producing foreign proteins, such as typhoid vaccine, have yielded satisfactory results, in a few, puncture of the lateral ventricle with injection of arsenaminized serum or corrosive mercuric chloride directly into the ventricle has arrested the progress. But none of these measures are certain of producing results, particularly if the atrophy is fairly well advanced.

PTOSIS OF UPPER EYELIDS

To the Editor—A man of about 50, without discoverable defects other than a deflected septum, consulted me because of ptosis of both upper lids. This condition had been coming on for two years and had got to the point where it interfered with his livelihood as a carpenter. There was no family history of anything of this nature, his general muscular system was excellent, and there was no way in which he could obtain compensation through malingering. The orbicularis oculi were apparently normal, and the patient was able to open his eyelids by using his own levators, and occasionally had to augment those muscles by wrinkling his forehead. I advised him to get lid supports to attach to the temples of his glasses after the manner devised by Dr. Burch of St. Paul and pictured in Atkinson's book on eye disease. If there is anything further you might have to advise, or any comments to make, I shall be glad to hear from you.

M.D., Kansas

ANSWER—Unless this patient has had a positive Wassermann reaction or a history of syphilis or has had influenza, it is difficult to know what may be the cause of the ptosis. Of course, a minute hemorrhage in that part of the third nucleus supplying the levator palpebrae might have occurred. For the latter two conditions no treatment is of avail. The patient should have a test for syphilis. If this is negative the Eversbusch operation (shortening the levator palpebrae) may be considered. Spectacles are of little value in such cases.

CARE OF SKIN AROUND FECAL FISTULA

To the Editor—One of the most bothersome things that physicians are called on to take care of is the treatment of the skin during the discharging period of a fecal fistula, whether from the large or the small intestine, but of course much more with the latter. There are few conditions, largely because they extend usually over a long period, that give the patient more discomfort and the physician and nurse more worry and anxiety than this condition.

I have had some personal experience with this, and as a result ran the gamut of all types of applications. I could find with but little benefit ointments, grease, powders, mucin paste, mercurochrome crust, methylene blue paint. Bronze powder is a good protector but has practically no effect after the erosion has taken place and is consequently of little use in the passageway from the skin to the intestine, which is particularly a source of a great deal of discomfort. During the course of these investigations, I happened to remark that it felt like a burn and my wife asked me why I did not treat it like a burn and use tannic acid, which I have been doing with more comfort than with all of the other treatments put together. This is used as a 10 per cent spray and allowed to dry, a heat lamp being used to accelerate the drying and several coats applied. Of course, it does not last a great while, but ordinarily two or three applications a day will carry one through and relief is instant.

Following an article by Dr. Guido, I used tooth normal hydrochloric acid, but the discomfort from the irritation of even this weak solution on the nerve ends in these raw spots was quite intense and it is hardly practical for an ambulatory patient, for to be effective the dressing should be changed frequently and kept moist with the acid solution. Along the lines suggested by Dr. Guido that the benefits come from neutralizing the discharge, and because of the constant irritation plus the digestive action on the skin, I began using boric acid powder and boric acid powder incorporated in zinc oxide, about 10 per cent strength, which I have found to be very effective in preventing this disagreeable irritating effect of the discharge.

GEORGE A. PRATT, M.D., Neenah, Wis

New Hampshire September Report

Dr Charles Duncan, secretary, Board of Registration in Medicine, reports the oral, written and practical examination held in Concord, Sept 13-14, 1934. The examination covered 10 subjects and included 70 questions. An average of 75 per cent was required to pass. One candidate was examined and passed. Nine physicians were licensed by reciprocity and three physicians were licensed by endorsement. The following schools were represented:

Book Notices

Textbook of Materia Medica and Therapeutics. By A. S. Blumgarten, M.D., F.A.C.P., Associate Attending Physician to the Lenox Hill Hospital Sixth edition Fahrhold. Price, \$3. Pp. 791, with illustrations New York. Macmillan Company, 1934.

This book, to assist in the study of materia medica, based on the author's twenty-five years' experience in the teaching of nurses, has been completely revised. The author aims to help the student-nurse to "observe the effects of drugs on patients, to recognize their earliest toxic symptoms, to be helpful to the physician in understanding what his objective is in prescribing various remedies, and to administer them in such a manner that the maximum effects possible may be obtained. . . . The modern nurse," he says, "is no longer merely the gentle attendant at the sick bed, able to perform only a few practical duties, but she is now also a watchful trained observer of symptoms of disease, of the development of complications, and of the effects of drugs and their poisonous symptoms." The text emphasizes effects, the site of action being of secondary importance to the nurse, which is an improvement in nurses' teaching to be devoutly thankful for. Many books on materia medica for nurses—obviously abstracts of books on pharmacology for medical students—waste a great deal of time and attention of the pupil nurse with discussions on the site of drug actions, which are of possible value to the prescribing physician but of no use whatever to the nurse. Particularly interesting are the ward practice questions, at the end of each chapter, which are intended to enable the nurse to record her ward experience and correlate it with the facts she has learned from the text. One cannot help wishing that medical students might have similar opportunity. The chief criticism that must be offered is that the book is too exhaustively thorough. The author "gives the whole bakery to a person asking for bread."

A Handbook on Diabetes Mellitus and Its Modern Treatment. By J. P. Bose M.B., F.C.S., in Charge, Diabetes Research, Calcutta School of Tropical Medicine Second edition. Cloth. Price, Rs. 6/8 Pp 232, with illustrations. Calcutta: Thacker, Spink & Company, Ltd, 1934

This book contains comprehensive and yet brief discussions of all the principal phases of the subject of diabetes. The material is presented in an orderly manner and with a delightful English style. The author is a native of India, educated in Calcutta and London, and for many years the physician in charge of the diabetic department of the Carmichael Hospital for Tropical Diseases in Calcutta.

It is not generally known by Western physicians that the Hindu physicians were familiar with diabetes long before the first mention of it was made in the writings of Aretaeus. The fact that the urine contained sugar escaped the notice of all the early European writers but is mentioned in the "Charaka-Samhita," a compendium written by the renowned Hindu physician Charaka in the second century A. D. It appears further that Charaka selected his material from a much earlier work of Agnivesa, who again based his writings on the teaching of his master, Atreya (sixth century B. C.). In 500 A. D., Susruta described the symptoms of thirst, foul breath, voracious appetite and languor in the disease "madhu-meha," or "honey urine," and in the old Hindu medical literature lack of exercise and laziness are mentioned among the causative factors of the disease. It is made clear by the author that lack of exercise is an important factor today. Excessive ingestion of carbohydrate has been thought to be a cause of diabetes in India, but in Bose's opinion overeating combined with indolent habits is to be blamed more than the excess of carbohydrate alone. The poor working

class Indian, whose daily food consists of large quantities of rice, rarely has diabetes because he secures enough hard exercise to use all the sugar liberated from the starch he eats. The rich Indian is the one affected, the land owner, the lawyer and the merchant. This is due to a combination of ill balanced diet, overeating, disinclination for any form of exercise, excessive intellectual work, and sedentary habits. The Bengalee Hindus appear to be more prone to acquire the disease than members of any of the other races living in India. "What gout is to the nobility of England, diabetes is to the aristocracy of India."

Though there is no doubt that diabetes is much less common among children than among adults, it is not so very rare among Indian children. The youngest patient in the author's series was a boy aged 1 year and 4 months. The diabetic children in India, as has been noted in the Western countries, are usually taller than children of the same age and are unusually alert mentally, sometimes verging on precocity.

In large cities such as Calcutta, with well equipped hospitals and laboratories and trained workers in them, periodic examinations of blood sugar are readily obtainable, but the doctor in the distant "mofussil" towns and villages is handicapped in this regard. Therefore the author has devised and describes a simplified method for estimating blood sugar, a method providing results that agree to the second decimal point with those given by authenticated methods. He thinks it is unscientific and sometimes dangerous to treat patients without regard to the blood sugar level and refers to a number of cases of renal glycosuria treated with insulin with results just short of disaster.

The author's methods of treatment are sound and conservative, and despite the fact that the book is written on the other side of the globe and by one of an ancient race with which few American physicians are acquainted, it is one of the most instructive and readable treatises on diabetes that have appeared anywhere.

The Power to Love: A Psychic and Physiologic Study of Regeneration. By Edwin W. Hirsch, B.S., M.D., Associate in Urology, College of Medicine, University of Illinois. Cloth. Price, \$4. Pp. 363, with 5 illustrations. New York: Alfred A. Knopf, 1934.

In the development of this volume the author has consulted a vast amount of sexologic literature. That is apparent from the very nature of his references in the work. He begins by considering the physiologic mechanism regulating sex and follows with some attempt to convey an understanding of the various factors that may influence sex practice unfavorably. He next considers the various forms of impotence and frigidity, concluding his work with discussions of sex technic, systems of sexual control and a general discussion of potency. The references to the literature and the quotations indicate somewhat a lack of scientific judgment or an understanding as to what is established and what is merely theoretical in the sex field. Furthermore, in the section on sexual technic the author would seem to exaggerate somewhat the mechanization of a natural phenomenon. There seem today to be far too many works that endeavor to make a science out of what most normal young people find out for themselves with only a reasonable amount of opportunity. The classification of this work is difficult. It is not sufficiently scientific to attract the truly medical reader. Its discussions and deliberations are frequently, however, far too complicated and technical for the average layman, who perhaps requires the kind of information that it supplies, and yet its discussions are hardly such as to make the book suitable for a collection of erotica.

Rezeptbuch der Pflanzenheilkunde: Die Verwendung der Heilpflanzen und Kräutertees in der täglichen Praxis. Von Dr. med. S. Flamm und Apothekendirektor Ludwig Kroeber. Paper. Price, 10 marks. Pp. 188. Stuttgart & Leipzig: Hippokrates-Verlag G. m. b. H., 1934.

This book is essentially composed of two parts. The contents of the no doubt more important second or prescription part force one to look at the date of publication to make certain that it is not 1534, that this is not one of the "herbals" of the Middle Ages, and that it actually was published in the year of grace 1934. Starting with herb teas affecting metabolism and serving for "blood purification," some of which have a half dozen ingredients, it gives prescriptions for teas "for spring cure" with prescriptions of gradually increasing complexity up to seventeen

ingredients. These teas cure scrofula and rickets, gout and rheumatism, sugar [sic], arterial sclerosis, goiter and syphilis (!). Herb teas of the dim and distant past are actually resurrected for the cure of syphilis. It would be merely waste of valuable space to go on discussing the absurdities contained in this prescription part. What is interesting is that these "prescriptions" contain German herbs exclusively. The first part of the book might be considered an apology for the second part and it rather cleverly instances scientific facts, such as the superior pain-relieving qualities of opium as compared with morphine, to bolster up not only its gross and unscientific return to the use of crude herbs but of the polypharmaceutic mixtures of these. The wonder that such a book could be printed as a serious medical contribution in this age of alleged enlightenment is solved when one discovers that it is published by *Hippocrates*, a journal that attempts to bridge the gap between "school medicine" and "biologic medicine," between homeopathy and "nature cure," that aims to found a new German "heilkunde." Its motto is "Das dritte Reich will nicht Mediziner züchten, sondern Ärzte, die biologisch denken können" (the third reich does not want to breed mere medical men but physicians who can think biologically), a good motto, no doubt; but, if this book is a sample of the tendency of this new biologic medicine, it is quite evident that the progress is a movement backward into the Middle Ages, back to the herb teas of unfathomable complexity. The obvious purpose of this anachronistic "kräuterbuch" is to substitute for modern medicine based on international science a Nazi medical system based on the medical wisdom of the German aborigines.

Wish-Hunting in the Unconscious: An Analysis of Psychoanalysis. By Milton Harrington, M.D., Psychiatrist, Institution for Male Defective Delinquents, Napanoch, N. Y. Cloth. Price, \$2.50. Pp. 189. New York: Macmillan Company, 1934.

Here is a shrewd arraignment of psychoanalysis. The author is wholly out of sympathy with the freudian hypothesis and he contrives to condemn it out of the mouths of its sponsors. It is well and temperately done. It will make good reading for those who disagree with Professor Freud and perhaps wholesome reading for those who carry his theories to extreme degrees. The principal charges brought by Dr. Harrington against psychoanalysis are that it lays an unwholesome emphasis on sex as a motivation; that it succeeds only in the neuroses, in which any form of faith healing has been effective since time immemorial; that it fails totally in the psychoses; that its popular success is merely a passing phase "not to be taken as proof of either scientific or therapeutic value" but "nevertheless a very interesting psychological phenomenon." The author charges that psychoanalysis has contributed nothing to mental hygiene but, on the contrary, has postulated in effect that all mental hygiene is necessarily perverted. As an alternative to psychoanalysis he proposes the development of scientific psychophysiology, psychopathology and mental hygiene. Whether one agrees or disagrees with the author, it is a stimulating piece of work.

A Report on Cancer of the Skin. By Greta M. Thomas, M.D. An Inquiry Undertaken at the Instance of the Yorkshire Council of the British Empire Cancer Campaign Under the Direction of the Faculty of the General Infirmary at Leeds. Reports on Public Health and Medical Subjects, No. 70. Ministry of Health. Paper. Price, 2s. Pp. 130. London: His Majesty's Stationery Office, 1933.

The body of the report deals with the etiology of epithelioma, the duration of the tumor at the time of operation, and the results of operation at three, five and ten year periods thereafter. In five appendixes are tabulated the occupations of the patients, and in appendix 6 details are given of the cases transitional between rodent ulcer and squamous epithelioma. Appendix 7 gives the list of the lesions preceding each rodent ulcer, and appendix 8 the causes of death in patients dying from other causes than cancer. One of the particular aims of this investigation was to ascertain whether occupations other than those generally recognized as carcinogenic could be convicted of an evil influence in this direction. No such evidence was obtained. Lupus vulgaris was a frequent cause of epithelioma, twenty-five out of 161 cases in the series being caused by it, at an average age of 42, fifteen years earlier than the average age of the onset of the whole group. This is because of the early onset of lupus vulgaris. In spite of the fact that cancer of the lip occurred eleven times as often in men as in

women, with cancer of the lower lip twenty times as frequent as that of the upper lip, women had cancer of the upper lip more often than men. No explanation of this is offered. An outdoor occupation is shown to play a large part in the development of cancer of the lower lip in men. It is suggested that, besides exposure to the sun and wind, it gives a greater opportunity for pipe smoking. Another interesting observation was the frequency of phimosis as an etiologic factor in epithelioma of the penis, and the relative mildness of epithelioma in this region. Operation in the early stage gave a net survival rate of 80 per cent at the end of ten years. The report is a valuable one and should be available to all who are interested in skin epithelioma.

The Art and Principles of Nursing. By Amy Elizabeth Pope, R.N., and Virna M. Young, R.N. Fifth edition. Cloth. Price, \$2.75. Pp. 832, with 131 illustrations. New York: G. P. Putnam's Sons, 1934.

A new edition of the standard nursing textbook originally written by Anna C. Maxwell and Amy Elizabeth Pope is welcome. Miss Pope now has as a co-author Virna M. Young. The change in the title, which formerly was *Practical Nursing*, seems desirable because the book is for students working to become registered nurses and not primarily for practical nurses, though the latter would find it extremely useful. The present edition is comprehensive in scope, detailed in treatment, clear in description. Reasons for procedures are given, as well as instructions for the procedures themselves. There is a section on diseases that gives the nurse a background for her training without at the same time giving too much encouragement for self diagnosis. There are a few unfortunate minor errors, such as the old multiple scarification technic for smallpox vaccination, the recommendation of the proprietary antiphlogistine for packs, and the statement that blood is examined for spirochetes in the diagnosis of syphilis. The section on first aid is particularly good, perhaps because it is more profusely illustrated than any other section. All the illustrations are good, but some of the technical procedures that are not illustrated could with profit have been made the subject at least of diagrams. The book is well made, convenient to handle and well indexed.

A Primer for Diabetic Patients: A Brief Outline of the Treatment of Diabetes with Diet and Insulin, Including Directions and Charts for the Use of Physicians in Planning Diet Prescriptions. By Russell M. Wilder, M.D., Professor and Chief of the Department of Medicine of the Mayo Foundation, University of Minnesota. Fifth edition. Cloth. Price, \$1.75. Pp. 172, with 3 illustrations. Philadelphia & London: W. B. Saunders Company, 1934.

This is designed to tell the intelligent layman suffering from diabetes mellitus what he should know about the disease, its complications and treatment. It is intended for the patient who is under treatment by a physician, and the chapter on planning the diet is addressed to the latter. There is a surprising amount of information compressed into this small volume, including specific diets, recipes and food tables. The attention paid to the common exigencies of diabetic life, such as generally available menus while traveling, make the book particularly valuable.

Races, Nations and Jews. By Dr. Joseph Tenenbaum. Cloth. Price, \$2. Pp. 170. New York: Bloch Publishing Company, 1934.

In this book Dr. Tenenbaum treats a difficult social problem in the same way he would treat an obscure medical disease. In the first part of the book he discusses quite fully the underlying anthropologic and sociological factors that are etiologically related to antisemitism, which he regards as a serious social disease, from time to time reaching pandemic proportions. He reviews existing knowledge of the development of races and proves that there are no pure races. The Aryan race and the Nordic race have no sound basis in history of man's development; he regards them as entirely mythical, created by certain peoples to claim for themselves a superiority that is not based on scientific facts. Nations, too, cannot be defined by either language or territorial boundaries but are largely a state of mind. According to this point of view, he regards the Jews without a language and without a well defined country as one of the oldest and best defined nations who might play an important part in our general sociological definitions. He shows that whenever and wherever a people has broken with the laws of humanity and democracy, the Jew has proved a convenient scapegoat. The increasing antisemitism of today with its intense

form in Hitler's Germany is a manifestation of postwar social and economic disturbance. History has shown that the lot of the Jews quite parallels the course of democracy. The world, therefore, must be interested in the fate of the Jews and treat antisemitism as it does any other serious menace that threatens the safety of society.

A Textbook of Histology. By Alexander A. Maximow and William Bloom, Associate Professor of Anatomy, University of Chicago. Second edition. Cloth. Price, \$7. Pp. 662, with 530 illustrations. Philadelphia & London: W. B. Saunders Company, 1934.

Professor Maximow died in 1928 and the first edition of this important work was issued shortly afterward. The experience of four years with the volume has caused Dr. Bloom to recast it completely, using variations in type to emphasize the more significant information. Bibliographies are now included at the ends of the chapters. This histology was promptly accepted by teachers everywhere as a most useful work. Its illustrations are among the best developed in works of this character, and the publisher has aided in developing the reproductions to a high point of lucidity. The book is not ponderous either in its expression or in its appearance.

Sex-Hygiene: What to Teach and How to Teach It. By Alfred Worcester, A.M., M.D., Sc.D., Henry K. Oliver Professor of Hygiene, Harvard University. Cloth. Price, \$2.50. Pp. 134. Springfield, Ill., & Baltimore: Charles C. Thomas, 1934.

This collection of addresses by Dr. Worcester is interesting and valuable, but it could have been more appropriately titled. It is the philosophy evolved from a life in medical practice and teaching, but it is not an outline of what to teach about sex and how to teach it. Perhaps the most interesting of all the chapters is the first, not so much because of what it contains as because of when it was written. Almost any writer on sex would write such a chapter today, but few indeed would have been the hardy souls who would have exposed themselves to storms of lay and professional criticism as did Dr. Worcester by boldly stating in 1899 what even in 1934 has not had universal acceptance: that sex is inherently decent and not indecent, that girls as well as boys should know about sex, and that each sex should know something about the other. The conclusions drawn by the author are interesting; namely, that there is a physiologic basis for sex morality and not alone a moral or religious basis. This physiologic basis he conceives to be the responsibility for protecting the germ plasma that is entrusted to each individual. He judges sex morality on the basis of its effect on the germ plasma.

New Patterns in Sex Teaching: The Normal Sex Interests of Children and Their Guidance from Infancy to Adolescence. By Frances B. Strain. Cloth. Price, \$2. Pp. 242, with 2 illustrations. New York & London: D. Appleton-Century Company, Inc., 1934.

This is a useful and attractively written book. The author is a woman who is well versed in matters pertaining to sex education and, in addition, a mother who has found it necessary to give such instruction in a practical way. Here is a book that any mother can understand and which has been written so attractively and thoughtfully that it carries conviction. Various plans and suggestions are made in a way that insures their usefulness. The book is recommended for parents and to physicians who wish to be able to instruct parents in these matters.

A Nutrition Program and Teaching Outline Developed for Use in the Health Centers and Clinics of the Division of Child Hygiene, Department of Public Health, Philadelphia. Paper. Price, \$1. Pp. 156. Philadelphia: Philadelphia Child Health Society, 1934.

This outline should be useful to all teachers of nutrition. It gives a general summary of teaching points on nutrition and follows this with outlines on health examinations and corrections of defects, hot weather hygiene, child development and training, good eating habits, sleep and rest, good hygiene and constipation. Under the heading of "Food and Health," a daily food guide is given for various ages at moderate cost. Minimum and emergency nutrition, food allowances for a week, market guides, nutrition and diet during prenatal, infant, preschool, school and adolescent years, and nutrition in relation to the teeth are discussed. Chapters are devoted in detail to important classes of foodstuffs. The work is accompanied by a good bibliography and should be a valuable addition to the library of any teacher of health, hygiene or nutrition.

Röntgendiagnostik der Knochen- und Gelenkkrankheiten. Von Professor Dr. Robert Klenböck. Heft 3 (Abteilung Gelenkkrankheiten). Gelenks-osteomatosse und Chondromatose. Boards. Price, 22.50 marks. Pp. 228, with 194 illustrations. Berlin & Vienna: Urban & Schwarzenberg, 1934.

This book on osteomas and chondromas is written by the leading roentgenologist of Vienna, and one of the best known international roentgenologists. The subject is covered completely, with excellent illustrations of pathologic specimens and numerous roentgenograms, line drawings and tables. The bibliography is complete.

A Soldier in Science. The Autobiography of Bailey K. Ashford, Colonel M. C., U. S. A. With a foreword by General M. W. Ireland. Cloth. Price, \$3.50. Pp. 425, with 15 illustrations. New York: William Morrow & Company, 1934.

The death of Dr. Bailey K. Ashford was recorded in the obituary columns in *THE JOURNAL*, November 10, page 1467, where in the usual brief fashion the record was summarized of a distinguished career, which Dr. Ashford himself describes with all its romantic and dramatic aspects. His work in the tropics, his association with the army medical corps in France, his scientific research and his contributions to the control of certain forms of tropical disease are given due consideration in this record of his career. Dr. Ashford is able to look at his own research with proper abstraction; and his discussions of the development of our knowledge of hookworm disease and of sprue are written with the point of view of the scientist rather than of the claimant to priority. It is interesting to realize that one of the latest applications of a scientific discovery, namely, the application of liver extracts to the control of some of the tropical anemias, is considered in this book.

The Dangerous Age in Men: A Treatise on the Prostate Gland. By Chester Tilton Stone, M.D. Cloth. Price, \$1.75. Pp. 105. New York: Macmillan Company, 1934.

This review contains the combined opinions of a layman and a medical man. The book divides itself into two parts, in one of which Dr. Stone attempts to give medical information to the layman. As in some such cases, the author has a tendency to be confusing. He uses terms that cannot possibly be recognized by the lay reader, nor can the various kinds of complications be identified. The other part of the book, running concurrently with the medical phase, is quite commendable. Not only does Dr. Stone show sympathetically that troubles of the prostate gland are natural and nothing to be secretive about, but on reading the book the would-be patient would be likely to seek good medical advice. Had Dr. Stone omitted the technical medical pages and left the simple human statement of the trouble and the intelligent advice to take care of it in its early stages, it would not, like so many lay medical books, create fear and confusion in the reader's mind.

John Keats's Anatomical and Physiological Note Book. Edited by Maurice Buxton Forman. Printed from the Holograph in the Keats Museum, Hampstead. Cloth. Price, \$4.75. Pp. 68. New York & London: Oxford University Press, 1934.

This is a reprinting of the notes kept by the poet John Keats when he attended the lectures at Guy's Hospital. The original is on exhibition at the Keats Museum at Hampstead. It offers an interesting sidelight on one phase of the career of a literary immortal who was also a physician.

Postures and Practices During Labor Among Primitive Peoples: Adaptations to Modern Obstetrics with Chapters on Taboos and Superstitions and Postpartum Gymnastics. By Julius Jarcho, M.D., F.A.C.S. Cloth. Price, \$3.50. Pp. 175, with 129 illustrations. New York: Paul B. Hoeber, Inc., 1934.

This volume was developed by the author as a companion book to his earlier work on the pelvis and obstetrics. It is largely a picture book with a brief text covering the customs and taboos of primitive peoples. It is remarkable how many extraordinary postures have been developed among races living under the conditions of nature, in all of them an attempt being made to find such relief as can be secured from the pain associated with the obstetric procedure. The author discusses not only the various practices and postures used by the human being but also those of primates. He has added chapters on urine and hormones and on postpartum gymnastics. The book should be useful and of interest to obstetricians and ethnologists.

Medicolegal

Infanticide: Necessary Proof of Live Birth.—The defendant was convicted of the murder of a new-born child and appealed to the Supreme Court of Georgia. There was no direct evidence that the child was born alive. Eight or nine days after the infant had been buried, a physician performed an autopsy. The body was at that time badly decomposed. One lung was removed and subjected to the hydrostatic test and otherwise examined, and the physician testified that in his judgment the child breathed after it came into the world. The Supreme Court cited *Rex v. Enoch*, 5 C. & P. 539, a case of infanticide, to the following effect:

The child might have breathed before it was born, but its having breathed is not sufficiently life to make the killing of the child murder. There must have been an independent circulation in the child, or the child cannot be considered as alive for this purpose.

In *Morgan v. State*, 148 Tenn. 418, 256 S. W. 433, the court pointed out that gas in the lungs as a result of decomposition would cause them to float just as air would, adding:

Ordinarily, if the child has breathed, this would show independent life. But this test is not infallible. Sometimes infants breathe before they are fully delivered, and sometimes they do not breathe for quite a perceptible period after they are delivered. Generally, however, if respiration is established, that also establishes an independent circulation and independent existence.

The testimony of the physician in the present case that in his judgment the child breathed after it came into the world, said the court, was not an unqualified statement of opinion that the child was born alive or that it had acquired "independent circulation and existence" separate from its mother. The testimony of the physician as a whole was consistent with the theory that the child was born dead, and there was no other evidence tending to show that it was born alive. The evidence was insufficient to establish the crime beyond a reasonable doubt, and the trial court erred in refusing a new trial.—*Shedd v. State (Ga.)*, 173 S. E. 847.

Hospitals: "Inmate of Hospital" Construed.—The deceased, in an application for life insurance, stated, among other things, that he had never been an "inmate" of any hospital or sanatorium. In a suit by the beneficiary to recover the benefits provided in the policy, the evidence disclosed that the deceased, prior to the time he applied for insurance, had been admitted to hospitals on several occasions, principally for observation or for diagnostic purposes. The beneficiary contended, apparently, that, because the deceased had received little if any treatment in the hospitals, he was not an "inmate" of the institutions. In disagreeing with this contention, the United States circuit court of appeals, seventh circuit, said: "there is much said about the meaning of 'inmate' of a hospital. True this defendant [sic] received principally examination and observation and only little therapeutic medicine. But a hospital is a place where ailments are cared for. A well man has no place therein. The first step in modern treatment of any complicated physical trouble is the ascertainment of the cause. Therein modern medical science has progressed; it seeks first to diagnose, then to cure. Here for a year or more skilled physicians, in various hospitals and clinical tests, had, by use of modern hospital facilities, endeavored to perform the first step, and failed. The insured had a complicated condition; he was not cured; indeed his trouble was not even yet satisfactorily diagnosed. Can his beneficiary, in the face of this hospitalization, this consultation of physicians, this oft-repeated and always frustrated attempt to analyze his ills, insist that he was not an inmate because the hospital authorities never attempted to cure him? Is hospitalization any less hospitalization because its purpose is the first step in treatment of physical ills, diagnosis, instead of the second, cure? We know of no justification of a definition of the word 'inmate,' restricting the meaning by the limitation 'not for diagnosis, but for therapeutic treatment.'" The judgment of the district court for the beneficiary was reversed.—*Aetna Life Ins. Co. of Hartford, Conn., v. Perron*, 69 F. (2d) 401.

Workmen's Compensation Acts: Death from Coronary Thrombosis Compensable.—On Sept. 7, 1929, the employee, 42 years old, obtained employment with the Ford Motor Company, Portland, Ore., after a physician for the employer had examined him and pronounced him "as fit for any work." While engaged, October 5, in piling automobile wheels, weighing about 20 pounds each, six of the wheels fell from approximately 8 feet and landed edgewise on the employee's back, flooring him and badly bruising his neck, back and shoulders. Before the accident, the employee was able to perform his work speedily and efficiently, and had considerable "pep." Afterward, he became sluggish and was unable to keep up with his work; but he continued on the job for a portion of the time until October 23, when he became so ill that he had to quit and go home. He lounged about the house until about October 28, when he died suddenly. The cause of death, as disclosed by a postmortem examination, was "coronary thrombosis with infarction." In a proceeding under the workmen's compensation act of Oregon, the circuit court, Multnomah County, awarded compensation to the claimant, and the state industrial accident commission appealed to the Supreme Court of Oregon.

The theory of the claimant was that the injury of October 5 produced an embolus, which was carried through the blood stream until it eventually reached the right coronary artery, where it increased and formed a thrombus, producing death. The commission, on the other hand, contended that the death was due to a thrombus, caused by arteriosclerosis, and that it had no connection with the accident. Both theories were supported by the testimony of expert witnesses. This situation, said the Supreme Court, left the question for the determination of the jury, and, in the opinion of the court, the testimony warranted a finding that there was a causal connection between the accident and the death. Whether the accident directly caused the death or whether it aggravated or accelerated a disease condition was considered by the court to be immaterial. Compensation may be awarded, although there was a preexisting disease, if that disease was aggravated and accelerated by an accidental injury arising from the employment and was the proximate cause of the disability or death. The judgment of the circuit court, awarding compensation, was affirmed.—*Armstrong v. State Industrial Accident Commission (Ore.)*, 31 P. (2d) 186.

Malpractice: Limitation of Actions; Accrual of Right of Action.—In performing an operation on the plaintiff in 1926, the defendant-physician left gauze in her abdominal cavity. He continued to treat her thereafter but did not inform her that gauze had been left in her abdomen. The gauze was discovered and removed during the course of another operation in 1933. She then instituted suit against the defendant. The trial court dismissed the action, holding that the Arkansas statute of limitations required that tort actions be instituted within three years after the accrual of the right of action. The plaintiff thereupon appealed to the Supreme Court of Arkansas.

A physician, said the Supreme Court, must exercise that degree of care, skill and learning ordinarily possessed and exercised by members of his profession in good standing in the community in which he practices. It cannot be said as a matter of law, continued the court, that the defendant did not know that the gauze was left in the patient's abdomen, because, under the rule just stated, he was required to exercise ordinary care in the performance of the operation and when thus measured might have known that the gauze was left in the patient's body. If, in the exercise of ordinary care and skill, the physician knew that the foreign substance was left in her body, it then became his imperative duty to apprise her of that fact. The physician had the duty resting on him, not only to perform the operation with ordinary care and skill, but also to make immediate disclosure to his patient of any injury inflicted through his negligence. His failure to make such disclosure was a continuing act of negligence. He was under a constant and daily obligation to use ordinary care and skill, and if by omission or negligence he left a foreign substance within the walls of the abdominal cavity, it behooved him to afford timely relief. The Supreme Court concluded, therefore, that the act of the physician in leaving the gauze in the abdomen and his

failure to apprise his patient thereof "were such fraudulent concealments and continuing acts of negligence" as would suspend the statute of limitations until the physician performed his duty of removing the foreign substance or the patient learned, or should have learned, of its presence.

The ruling of the trial court dismissing the action was therefore reversed and the Supreme Court ordered a trial of the cause.—*Burton v. Tribble (Ark.)*, 70 S. W. (2d) 503.

Accident Insurance: Death from Infected Abrasion Due to Prolonged Use of Bedpan.—The defendant insurance company issued a policy providing double indemnity if Hoff should die directly and exclusively from bodily injury effected solely through external, violent and accidental means. Hoff was taken to a hospital suffering from general pains in the arms and legs, and a paralysis of his lower limbs developed. Through an attendant's negligence, he was left on a bedpan for over four hours. When the pan was removed, an abrasion about three inches in diameter was found near the base of his spine. The abrasion became infected, toxemia developed and the insured died about a month later. An autopsy revealed a spinal cord tumor. The physician who performed the autopsy testified on behalf of the beneficiary of the policy, in a suit to collect the double indemnity benefits, that the infection was the sole cause of death and that the tumor was the contributing cause only so far as it induced Hoff to enter the hospital and thus afforded the opportunity for him to be injured. The defendant introduced no medical testimony. From a judgment for the beneficiary, the insurance company appealed to the Supreme Court of Michigan.

The defendant contended, apparently, that the injury, which ultimately resulted in death, was not produced by "accidental means." In defining the term "accidental means," the court referred to *Wheeler v. Title Guaranty & Cas. Co.*, 265 Mich. 296, 251 N. W. 408, where it was said:

Where the effect is not the natural and probable consequence of the means which produce it—an effect which does not ordinarily follow and cannot be reasonably anticipated from the use of the means, or an effect which the actor did not intend to produce, and which he cannot be charged with a design of producing—it is produced by accidental means.

Ordinarily, said the Supreme Court, the use of a bedpan will not result in injury. The insured can hardly be held to have foreseen the possible consequences of his prolonged presence on the bedpan, since his paralyzed condition made it impossible for him to experience discomfort or pain. The abrasion and infection were not the natural and probable consequences of the use of the bedpan and could not have been reasonably anticipated, nor was the infection a result which the insured or the hospital attendants intended to obtain, but rather the consequences of inadvertent neglect. The injury was effected through "accidental means," in the opinion of the court, and was the proximate cause of death. The judgment in favor of the beneficiary was affirmed.—*Hoff v. Mutual Life Ins. Co. of New York (Mich.)*, 254 N. W. 137.

Malpractice: Release of Tort Feasor as Bar to Action Against Physician.—If a person injured through the negligence of another exercises due care in the selection of a physician to treat his injury, the malpractice of the physician which aggravates or increases the injury is regarded in law as a part of the original injury, for which the original wrongdoer is responsible. A release by the injured person of his right to recover damages from the original wrongdoer operates as a bar to an action for malpractice against the physician.—*Tanner v. Espey (Ohio)*, 190 N. E. 229; *Milks v. McIver (N. Y.)*, 190 N. E. 487.

COMING MEETINGS

American Academy of Orthopedic Surgeons, New York, Jan. 14-16. Dr. Philip Lewin, 104 South Michigan Boulevard, Chicago, Secretary.
American Association for the Study of Neoplastic Diseases, Baltimore, Dec. 27-29. Dr. Eugene R. Whitmore, 2139 Wyoming Avenue, N.W., Washington, D. C., Secretary.
Society of American Bacteriologists, Chicago, Dec. 27-29. Dr. James M. Sherman, Cornell University, Ithaca, N. Y., Secretary.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

American Journal of Medical Sciences, Philadelphia

Hodgkin's Disease, Infection or Neoplasm.—Krumbhaar examined the tissues of thirty-three fatal cases diagnosed as Hodgkin's disease, of which none revealed a demonstrated progress from the granulomatous to the sarcomatous picture of Hodgkin's disease—Ewing's Hodgkin's sarcoma. In three there was strong probability that the condition was sarcomatous from the beginning or reasonable doubt as to whether Hodgkin's disease or lymphosarcoma in one or another form was under consideration. Evidence for an associated active tuberculosis was present in three cases but may well have been overlooked in others. The author states that his material lends no support for the primary neoplastic nature of Hodgkin's disease, unimpressive evidence in favor of a causative relationship of tuberculosis and no examples of progress from the granulomatous to the neoplastic type of Hodgkin's lesion. It brings one back definitely to the probable basis of a granulomatous infection of unknown etiology. He reviews the accumulated evidence bearing on the infectious versus the neoplastic origin of Hodgkin's disease. While it is apparent that the nature of Hodgkin's disease remains obscure, the preponderance of evidence favors the infectious theory, with some promising support for its inclusion

among the virus diseases. The use of the term Hodgkin's disease (rather than lymphogranuloma or lymphoblastoma) and the restriction of its use solely on a pathologic (not a clinical) basis is indicated.

Acute Agranulocytosis Complicating Kala-Azar.—Zia and Forkner observed that agranulocytosis occurred in four of twenty-six consecutive cases of kala-azar. In three of these the agranulocytosis was acute, in one of which it was recurrent. The period of observation of the fourth case was too short to determine whether the attack was acute or chronic. Acute agranulocytosis is a common and previously unrecognized complication of kala-azar. It is only as the result of frequent and careful studies of the blood that this complication may be detected and appropriate treatment given. The syndrome of acute agranulocytosis as it occurs in kala-azar, pyogenic infections and agranulocytic angina is less conspicuous when it occurs as a complication of kala-azar than when it is associated with agranulocytic angina, owing to the fact that attacks of the latter disease come on abruptly during a period of good health, whereas the agranulocytosis of kala-azar occurs in patients who are already quite ill. The first clinical manifestations of the syndrome are weakness and a feeling of exhaustion coming on rather rapidly over a period of from twelve to seventy-two hours. White blood cell counts at this period show an increasing leukopenia with a decrease in the number of granulocytes. The symptoms become more intense and the leukocytes frequently decrease to from 500 to 2,000 cells per cubic millimeter, with a total absence of neutrophils or the presence of a few. After from twenty-four to ninety-six hours more alarming symptoms appear, consisting of high fever, redness and tenderness of the mucous membranes, soon followed by rapidly extending ulceration accompanied by localized pain and marked general discomfort. Unless an increase in the number of neutrophils occurs either spontaneously or as the result of treatment, the symptoms and signs progress and the patient often succumbs as the result of infection. If the leukopenia subsides and the granulocytes increase progressively before severe secondary infection has occurred, a remission takes place in which there is rapid recovery.

Tolerance Test for Angina Pectoris.—The exercise tolerance test of Riseman and Stern makes use of a two-step staircase. They have found that the majority of patients suffering from angina pectoris develop typical attacks when exercising on the two-step staircase under standard conditions. When the test is repeated, the same amount of exercise invariably precipitates an attack in the same person, provided the standardized conditions are reproduced. To obviate the necessity for training and to minimize the effect of excitement, the patient is allowed to choose his own rate. Exercise on the two-step staircase is so similar to acts performed in daily life that the emotional factor is minimized. In seven of thirty cases, however, they found that at the time of the first test angina was developed after considerably less exertion than at subsequent tests. This discrepancy was due presumably to excitement and existed only at the time of the first test. The test is performed in a room the temperature of which is adjusted to between 45 and 55 F. The patient is tested at least one hour after a light meal or before breakfast on a day during which he has not experienced an anginal attack. The results are compared with single tests on other days. The exercise consists in repeatedly walking up and down the two-step staircase. The patient continues the exercise until he develops an attack of angina pectoris severe enough to cause him to stop. The number of times the patient mounts the staircase, that is to say, the number of trips performed, is recorded with a tally counter. The rate and the duration of the exercise are measured with a stopwatch. The exercise performed under the standard conditions of the test induced attacks in thirty-four of fifty-seven cases. These attacks were precisely like those experienced in daily life. When the standardized test was repeated, even months later, the same amount of exercise again precipitated an attack in the same person. Nineteen patients did not develop an attack under the standardized conditions. The diagnosis of angina pectoris eventually proved to be exceedingly doubtful in all but one. The amount of exercise necessary to precipitate attacks of angina pectoris in patients with this condition is influenced by various environmental factors. The test affords a means of investigating angina pectoris

and is of distinct value as an aid in diagnosing doubtful cases and in evaluating both the condition of the patient and the results of therapy.

Effects of Quinine Derivatives on Pneumococcus.—The work of MacLachlan and his associates confirms what Miura and Okamoto stated in reference to the superior protective power of ethylapoquinine over ethylhydrocupreine in experimental pneumococcal infection of mice. Ethylapoquinine varies considerably in its toxicity, depending on its chemical purity. The lessened toxicity fortunately does not diminish its protective power. These variations in the different samples of ethylapoquinine must be taken into consideration in interpreting the results of experimentation, and this must be remembered if later the derivative is to be used clinically. The estimation of the degree of levorotatory power in ethylapoquinine has been of value as a physical test for the toxicity of the derivative. The chemists believe that this physical property will be of great aid in the actual preparation of this substance, which may be toxic in its action on animals if impure. Of the two new derivatives, hydroxyethylapoquinine is the more important. This preparation has less toxicity than any of the ethylapoquinines and greater antipneumococcal power than any of them except ethylapoquinine (Japan). This preparation was as toxic as ethylhydrocupreine. The low toxicity of hydroxyethylapoquinine combined with its high protective power as indicated by the experimental results show it to be superior to the ethylapoquinines. Hydroxyethylhydrocupreine is the least toxic and, although its protective action is not as great as any of the other derivatives, its low toxicity makes the compound of definite interest.

Creatine and Creatinine Metabolism in Myopathies After Amino Acid Therapy.—Beard and his associates studied the creatine and creatinine excretion in the urine before and after the institution of amino acid therapy of thirty patients suffering from various myopathies. Both subjective and objective clinical improvement were observed in ten patients and subjective improvement in only seven patients whose creatine excretion rose from 50 to 200 per cent above that of the control period, provided this increased creatinuria soon disappeared or returned to the control level. In four other cases, the progress of the disease was arrested. No clinical improvement took place in thirteen cases, nine of which presented neuromuscular conditions, in which increased creatinuria was absent or less than 50 per cent above that of the control period. The results of these studies again confirm the authors' view that both creatine and creatinine may have an exogenous origin from the amino acids of the diet. Amino acid therapy had little effect on the distribution of nitrogen in the urine of three patients in the form of the total, urea, ammonia, uric acid and undetermined nitrogen. The increase in creatine and creatinine excretion was affected in only one of these cases. The authors present evidence that the lower motor neuron (tropic unit) with the muscle it innervates must be functionally intact for creatine formation from the amino acids.

Keratoplasty.—Castroviejo maintains that homokeratoplasty in human beings can be accomplished successfully when a suitable technic is followed. The principal features of the technic that he gives are: (1) to obtain a rectangular graft, 4 mm. square, corresponding exactly in size and with beveled edges

in both the transplant and the opening in the cornea of the recipient, with the anterior surface of the graft larger than the posterior surface, and (2) the use of conjunctival flaps to hold the transplant in position, giving a gentle uniform pressure, accelerating the process of healing and furnishing necessary nutrition while cicatrization takes place during the first few days. The conjunctival flaps also make a water-tight union favoring the prompt restoration of the anterior chamber and they offer the best possible protection for the graft and the eye in case the former becomes partially detached or does not heal. He believes that the technic of partial penetrating keratoplasty will give the best results in those eyes in which the whole pathologic condition is limited to the cornea, in which the leukoma is not dense and in which there are zones of slightly scarred or nonscarred cornea surrounding the transplant. In eyes with dense corneal leukomas in which the transplant is entirely surrounded by dense scar tissue, in those with aphakia and loss of vitreous during the operation, hypertension, and so on, the results cannot be expected to be so brilliant, but, since the vision in these eyes is limited to light perception and projection, or only perception, and the corneal transplantation offers the only means to improve the vision, operation is advisable. Eyes with heavy scarring of the conjunctiva round the cornea are predisposed to glaucomatous attacks; hence iridectomy previous to corneal transplantation should be performed. Transplants should be obtained from enucleated eyes in which the cornea has been unaffected. Enucleation of the donor's eye should be performed, if possible, under general anesthesia to avoid injury of the corneal epithelium, which almost always occurs when local anesthesia is used. Eyes of young people seem to furnish better material for transplantation than those of older persons. The importance that should be ascribed to blood grouping in corneal transplantation is to be determined when the operation has been performed in a large number of cases. Blood grouping was made in the last six cases reported and in each instance it was found to be different in the donor from that in the recipient. In examining patients with dense leukomas extending over the whole area of the cornea, posterior and anterior transillumination is the most valuable method.

Carcinoma of Portio Uteri.—Schiller believes that about 90 per cent of all uterine carcinomas arise in the portio vaginalis; therefore it is necessary for early diagnosis that one know exactly how a beginning carcinoma of the epithelium of the portio looks clinically on examination with the speculum. To this end, the author has submitted systematically to histologic examination in radial sections the portio of every uterus that was operated on in his clinic. Among them he found a number

of beginning carcinomas. The first stage shows a small carcinomatous coating, directly at the external os, of the same thickness as the existing normal epithelium and standing in direct connection with the normal epithelium, but sharply demarcated from it. There is complete absence of deep penetration and of superficial breaking down. The second phase shows one or two small cones penetrating downward, but still no ulceration; in the third stage there is superficial breaking down and growth into the deep parts through the penetration of cones into the stroma, and greater extent on the surface. In the third phase all the characteristics of the advanced carcinoma are seen, except that the proportion of that part which is in the deep tissues and that part which is on the surface is greatly in favor of the latter, which often accounts for nine tenths of the entire carcinomatous mass, while only one tenth has grown downward. In the further development of the carcinoma to the forms long known and studied the deep growth increases disproportionately and the superficial breaking down makes further progress, while the carcinomatous coating at the margin forms only a small fraction of the whole carcinomatous mass or finally disappears altogether. The problem of the rapid diagnosis of such a beginning carcinoma on speculum examination is made possible by the staining properties of the so-called Gram's solution, consisting of one part of iodine to two parts of potassium iodide and 300 parts of water. It causes fine differences to stand out more distinctly and gives sharper differentiations than the more rapidly acting but much more diffusely staining compound solution of iodine. If any place remains white or unstained, it is suggestive of carcinoma, but failure to take the stain is by no means definitely specific for carcinoma. There are other pathologic conditions in which the epithelium loses its glycogen content and consequently remains white and unstained after painting with iodine. The decision whether carcinoma or one of these other noncarcinomatous pathologic changes is present may in general be made only by histologic examination of the suggestive epithelium.

Replacement of Uterus After Delivery.—Drosin has found that, no matter how careful the technic employed in the delivery of the child and the expulsion of the placenta, the uterus with its supports and adnexa is still left in a state of distortion and on a level so low in the pelvis that it cannot always rise spontaneously out of it. Help on the part of the attendant is therefore indicated. The fingers should be placed above the symphysis and pressure exerted at first in a direction downward and backward and then backward and upward, and, as the uterus rises and anteverts, it is thus sustained for a few minutes until it is firmly contracted. As a result of this procedure the uterus becomes and remains contracted firmly and is raised out of the pelvis to a relatively normal state of anteversion. The uterine supports and vagina are helped to regain their normal tonicity, and hemorrhage, subinvolution, prolapse and retroflexion are minimized or obviated entirely. The result of this procedure as a routine is that it diminishes the incidence of postpartum retroversion of the uterus. With this method the author has rarely seen a puerperal retrodisplacement of the uterus except when there was a history of such a displacement prior to pregnancy. Hence he urges the routine use of this method at the time of labor.

Method to Avoid Skin Grafting in Breast Amputations.—To avoid skin grafting in breast amputation, Baldwin removes the breast, underlying muscles, axillary glands and so on by the usual method. If the cancerous tissue is so limited that the surgeon can make a safe and thorough removal and still leave sufficient tissue, the wound is closed in the ordinary way; but if the edges of the wound cannot be approximated, two transverse incisions are made directly outward from the open wound, the upper one parallel with the clavicle and the other at a suitable point below. These incisions are extended as necessary and the flap is detached from the chest by free dissection from the chest muscles. The distance to which the flap shall be separated must depend entirely on the necessity of the case. A sufficient piece of each of the two corners is removed, and the entire flap is then pulled over the exposed surface and attached by interrupted sutures, usually of silkworm gut, to the opposite edge of the wound, with approximation of the skin between these sutures by continuous number 2 chromicized catgut. If necessary a buttonhole is made, through which are drawn one or

two cigaret drains, to be removed in a few hours. A snug bandage is then applied round the entire chest. Healing occurs promptly, with a minimum of tension.

Normal Shadow of Peripheral Nerves and Pathologic Change in Injury and Tumor.—By injecting thorium dioxide sol (thorotrast) into the ulnar nerve, Saito roentgenographed the nerve for a maximal length of 39 cm. The roentgenogram revealed not only the shadows of the nerve fibers but also the internal and external sheaths of the nerve. It is therefore quite possible to use it for neurohistography. If it is applied to an injury of the nerve, it will clearly reveal the shadow of the injured part. The opaque substance injected into the periphery will not infiltrate into the center over the scar on the nerve caused by the wound. So a defect in the shadow of the nerve will be visualized naturally at the site of the scar. The author believes that this method will be of great help in roentgenologic diagnosis in cases of injury to nerves. If it is applied to the diagnosis of neuroma, it will not only show the form of the neuroma itself but also reveal its structure, together with the stem of the nerve penetrating into the neuroma. Therefore it should be useful in indicating treatment, yet it does not interfere in any way with the function of the nerve nor produce any after-effects such as neuralgia. The author recommends the procedure as the best method of clinical diagnosis, having employed it in eleven instances.

The Monocyte.—Doan and Wiseman point out that the monocyte is an independent entity, with life cycle and functions specific to its own peculiar endowments. In tuberculosis the monocyte has been shown to reflect and to be an important part of the cellular reactions to the acid fast bacilli and more particularly to the lipoids elaborated by this group of organisms. When appraised properly and interpreted in conjunction with the other cellular elements of the blood and in the further light of available clinical and laboratory data, prognosis in this disease and an accurate prompt estimation of the effectiveness of any given therapeutic measure become possible. In Hodgkin's disease, syphilis, pneumonia, the xanthomatoses and other pathologic states the monocyte if properly evaluated may contribute to the diagnosis of the disease and to the management of the patient. During the last four years the authors have diagnosed twelve cases of monocytic leukemia, and nine have been studied clinically with five necropsies. The problem of differentiating the leukemias is discussed.

Importance of Measuring Total Heat Production.—A knowledge of the basal metabolism is informative in many different problems, but its use as a basis for estimating the total production of heat is open to errors, which are sometimes so large that the observer is seriously misled; therefore Newburgh developed Benedict's study of the insensible perspiration. He has determined the total dissipation of energy by obese persons and compared these values with the calories of the diet. He then predicted the loss of weight and in that way convinced himself that all obese persons will lose weight when they are underfed and, what is more important, that these persons have invariably become fat simply and solely because they have eaten too much. The author has observed a patient of the type described by Cushing. The main characteristics are uniform

decalcification of the skeleton and adiposity of the upper half of the body. What superficially appears to be a localized accumulation of adipose tissue is in fact merely the configuration of a deformed skeleton. The author discusses the results of diet in this patient and also one who exhibited enormous localizations of adipose tissue whose initial weight was 560 pounds (254 Kg.). Both features are often credited with being signs of endogenous obesity. During the ensuing year his diet contained 300 calories a day. This effected a loss of weight of 287 pounds (130 Kg.). During the second year he received 600 calories daily and lost 93 pounds (42 Kg.). He now weighed 194 pounds (88 Kg.), a weight that was considered satisfactory for his height, and he was told to keep his weight stationary by judicious selection of his food. Nine months later he was told that he had lost a sufficient amount of weight, since he weighed the same amount. The ability to maintain the weight in the face of underfeeding is not the sole possession of obese persons, since the author reproduced it in the normal subject.

Treatment of Carcinoma of the Thyroid.—Pemberton believes that the most effective treatment of malignant neoplasms of the thyroid is the combination of surgery and irradiation. Because of important biologic differences, treatment of primary malignant tumors should be considered in accordance with the type and grade of the condition. The distinguishing clinical features of papillary adenocarcinoma are the low grade of malignant condition and the tendency for the disease to spread to regional lymphatic structures, where it may be confined without further dissemination for many years. Metastasis to the cervical lymph nodes is not a criterion of inoperability in this type, for radical surgical removal of the primary lesion, together with the involved nodes and in conjunction with postoperative irradiation, offers a good chance for cure. The essential clinical features of adenocarcinoma in fetal adenoma are, commonly, the low grade of the malignant process and the tendency for early dissemination of the carcinoma by way of the blood stream. Since lymph vessels are not involved until after the carcinoma has invaded the capsule, the presence of cervical metastasis in this type has a far graver prognostic significance than in the former. The presence of distant metastasis should not be construed necessarily as a contraindication to surgical removal of an encapsulated and obstructing malignant adenoma. Because of the tendency of metastatic malignant thyroid tissue to undergo marked differentiation, a single metastatic tumor may not seriously impair the health of the patient for years. The diffuse adenocarcinomas are of higher malignant grades than the preceding types and behave as diffuse adenocarcinomas situated elsewhere. Squamous epithelioma is rare and is highly malignant. The author's three patients with this type of growth died within a year of the operation. Sarcoma of the thyroid is rare and his four patients died within a year of the operation. The operability for 658 patients having a malignant growth of the thyroid seen at the Mayo Clinic was 48.8 per cent; of these 323 patients, fifty-six were treated by irradiation alone, ten lived five years or more, and, of the 267 patients who underwent partial thyroidectomy with or without postoperative irradiation,

127 lived five years or more. Adenomatous goiter is a precursor of malignant processes in a high proportion of cases and, therefore, a potential suggestion of malignant manifestation should be considered in every case of nodular goiter.

Omental Grafts in Abdominal Operations.—Graham states that in transplantation the thinnest and most vascular area of the omentum available should be used. The graft should extend beyond the raw area to be covered. Fine catgut sutures should be used and placed close together round the circumference of the graft. The raw edge of the great omentum should be turned under and sutured and should not be left in a thick mass to form undesirable adhesions. Fatalities have resulted from omission of this precaution. Success in the use of omental grafts is more likely to follow sharp dissection, a clean field, absolute hemostasis, prompt transfer and accurate suture of the graft to its new location. Resection of the entire omentum must be avoided, for gastro-intestinal hemorrhages occur in 4 per cent of all cases of total resection of the large omentum with a fatality of from 50 to 60 per cent, according to Karger. The author's experience leads him to believe that: 1. Free omental grafts will live, become adherent to the underlying attached structure, prevent adhesions to surrounding organs and, at times, even remain free from surface adhesions in the presence of pus. 2. They are hemostatic. 3. They aid in preserving peristalsis by the prevention of crippling and immobilizing adhesions. 4. They strengthen weak suture lines and resist infection. Twenty cases are reported in which omental grafts were used.

Primary Carcinoma of Bartholin Gland.—Lyle reports a case of primary carcinoma of the Bartholin gland in a woman of 30. He states that carcinoma of the Bartholin gland is as malignant as epithelioma of the vulva and unfortunately is also roentgen resistant. His study leads him to believe that the primary operation should consist of a wide excision of the vulva plus a secondary dissection of the inguinal and femoral glands, the excision to be carried out with the cold scalpel or the endothermic knife. In the advanced cases it is advantageous to destroy the original growth with endothermic coagulation and then proceed immediately with wide excision. The operation should be followed by a thorough local and regional irradiation. Healy, in his cases, applied radon seeds to the recurrence and later did a radical excision of the glands of the vulva. The success of any method rests on an early diagnosis: the diagnosis is not hard to make if the condition is kept in mind.

Streptococcus in Blood in Pemphigus.—Welsh isolated from patients with pemphigus a streptococcus having specific morphologic, cultural and fermentation characteristics and a characteristic cataphoretic mobility distribution curve. It has been found to be virulent for five species of animals and to produce lesions consistent with pemphigus in a fair number. Intradermal and subcutaneous injections of the dead organism into patients with pemphigus produces bullae. The different strains have been shown to be serologically identical. The

author describes the positive precipitin reactions between the nasopharyngeal washings from patients with pemphigus and the serums of animals immunized to the specific streptococcus. The reduction of the mobility of the respective streptococci by the serums from patients with pemphigus, dermatitis herpetiformis, lupus erythematosus and erythema multiforme, as compared with their mobility in a solution of sodium chloride, is applied as a differential diagnostic test between these four diseases.

Organic Luetin in Syphilis.—Barker performed the Kolmer luetin test on 627 syphilitic patients, from which he observed that a positive reaction occurs in 3.5 per cent of nonsyphilitic patients and can be induced by the ingestion of bromides and iodides, making the test unreliable. These observations, in addition to the fact that the luetin test is not as efficient in diagnosis in any stage of syphilis as the Wassermann test of the blood, is strong evidence that it is not practical. As to prognosis, there has not been sufficient study of organic luetin to warrant any definite conclusions. The fact that there is such a high proportion of negative reactions in cases in which the Wassermann reaction is positive would exclude it as a means of determining when a patient is cured of syphilis. In the field of therapy, organic luetin may be of practical value in treating persons with malignant and recurring secondary syphilis who do not respond to therapy with drugs. It has no influence on the Wassermann reaction of the blood and has an inconstant effect on gummatous lesions.

Acute Pemphigus in Granulocytopenia.—Fiala reports a case of acute pemphigus occurring in a patient with granulocytopenia. The degenerative changes of the mucous membrane of the throat and mouth seen frequently in granulocytopenia were pronounced. The sloughing and lesions of the entire large intestine, stomach and esophagus, however, were more like those of acute pemphigus—just as the cutaneous condition was typical of the textbook description of acute pemphigus. The cutaneous lesions occasionally described in granulocytopenia are of a different type from those encountered in the present case. The typical granulocytopenic lesions seem to be seated more deeply in the skin, usually with necrotic areas and crusts covering them and with definite enlargement of the regional lymph nodes.

Use of Thyroxine in Ophthalmology.—Jameson began an investigation in the hope of ascertaining whether thyroxine is a local metabolic stimulator of cell activation in ocular conditions—in which expectation Browning used it in his own eye—and whether it has active alterative qualities when applied locally. He administered thyroxine to about seventy-five patients. The effect in many of the acute cases has been so unusual as to be strikingly impressive. Some of the changes in the lens have remained stationary and some have improved materially, but in the short period of four months a definite decision as to how far lenticular opacities may be eliminated or influenced cannot be concluded. It is doubtful whether well developed nuclear changes can be influenced, but thyroxine may prove valuable in retarding incipient opacifications. Tension, undoubtedly, is reduced moderately, and thyroxine may prove

valuable in assuaging tension incident to tumefaction of the lens and has the advantage of not contracting the pupil. Cases of floating vitreous opacities have been helped noticeably and in a large proportion of keratitic conditions the improvement has been striking. The clinical evidence has appeared more striking to the author than natural improvement could account for, and he believes that it substantiates Browning's first conception of the establishment of thyroxine as a local metabolic stimulant and alterative.

Necrosis of Myocardium Induced by Orthophosphates.—McJunkin and his associates studied the effects of injected orthophosphates under conditions that prevented their rapid elimination and hence favored their accumulation in the blood. They found that myocardial necrosis may be produced by the injection of disodium phosphate into small nephrectomized rats. Lesions closely resembling the "phosphate" necrosis may be produced by the injection of calcium gluconate into nephrectomized rats. Both kinds of lesions show a tendency to early calcification. The chemical and histologic evidence indicates a close relationship between the necrosis and the deposition of calcium. In view of the tendency of the myocardial necrosis to become calcified, it may be assumed that the precipitation of calcium and phosphate ions represents a local condition of tissue in which the highly organized parenchymal cells of the myocardium cannot survive.

Tumors of Carotid Body.—Cragg reports a case of concurrent tumors of the left carotid body and both Zuckerkandl bodies. The similarity of their histologic appearance to that of paraganglionic tissue associated with the positive chromaffin reaction of the tumors of the Zuckerkandl bodies classifies them in the paraganglionic system. However, they were analyzed for epinephrine and found to contain none. Four other cases of tumor of the Zuckerkandl body have been reviewed and in none have a positive chromaffin reaction and a positive test for epinephrine occurred simultaneously. The author has found these two factors to be inconsistent in the examination of the suprarenal medulla, and the presence of epinephrine has never been demonstrated in the carotid body. Therefore he is inclined to believe that there is no definite association between the chromaffin reaction and epinephrine and that the presence of epinephrine is not essential in the classification of a tissue as a part of the paraganglionic system.

Histamine Iontophoresis.—Doane employed histamine iontophoresis in the treatment of a case of Buerger's disease with intermittent claudication, one of persistent hypertension with moderate kidney, cardiac and vascular damage, one of Buerger's disease, one of spasticity of the lower extremities and one of marked spastic arterial involvement of the lower extremities. The author states that by this method one has a means to effect

local hyperemia that is easily subject to control. The effect of this vasodilatation in thrombo-angiitis obliterans with intermittent claudication, in local ulceration due to a deficiency of blood supply and in painful muscle cramp or spasm, such as torticollis and lumbago, has been proved beneficial both subjectively and objectively. The ease with which localized areas can be treated by the use of histamine foils or even of gauze pads moistened with a 1:10,000 histamine solution makes possible a local counterirritant effect whenever the use of the immersion method is impracticable. No serious systemic responses were observed even when, as in one case, a fifth of the body was immersed in this solution. This patient evidently was not susceptible to histamine, since others in the group displayed systemic symptoms even though the amount absorbed must have been small. Clinicians have endeavored by the use of systemic vasodilators to procure localized responses. This has proved rather ineffectual, since splanchnic dilatation tended to counterbalance the local effect. It appears that by the immersion method the physician has a means by which effective treatment can be given to such conditions as diabetic ulcerations of the extremities, Raynaud's disease, Buerger's disease and many others of the vasospastic endarterial group. The author has not been able to learn how rapidly a known strength of histamine solution decreases in concentration as the result of ionization. It is reasonable to suppose that after several treatments a 1:10,000 solution may easily become so weakened that it has but a fraction of the original strength. It has been noticed repeatedly that after three or four treatments local and systemic response tends to become less and that these reactions recur when a fresh solution is employed.

Surgical Treatment of Facial Palsy by Autoplastic Nerve Graft.—Sullivan suggests that the nerve be uncovered at once whenever facial palsy immediately follows an operation on the mastoid, in order to determine the extent of the damage. The rewards of such action are manifest. Compression or slight injuries may then be remedied by decompression, or inspection will disclose the fact that the accident has destroyed or damaged a longer segment of the nerve. Immediate operation will permit a decompression of the nerve above or below the point of injury, averting the dire consequences of prolonged inflammatory compression, or a suitable graft may be introduced to replace the damaged segment. It is much better to explore and determine immediately the nature and extent of the injury than to be harassed by uncertainty.

Magnesium Chloride in Treatment of Cancer.—Craig cites a case which, during operation under tribrom-ethanol and chloroform anesthesia, disclosed a diffuse cancerous infiltration and edema of the larynx involving the epiglottis, the aryepiglottic folds, the arytenoids, the true and false vocal cords, the subglottic space and the trachea as far down as the tracheotomy wound. There was some improvement in the patient's general condition following the operation, which was attributed to the removal of the septic foci, but in spite of daily dressings and meticulous care, the laryngeal picture remained about stationary. The patient's condition was grave and the prognosis gloomy. As a last resort magnesium chloride was administered subcutaneously and combined with pepsin as a spray for the pharynx and with pepsin and glycerin as a dressing in the laryngeal cavity. The infiltration began to subside after the tenth treatment. The tracheotomy wound, which had been moth eaten and succulent in appearance, was now firm and healthy looking; the granulations in the laryngeal opening were white, healthy and glistening. The odor and cough had almost disappeared. The improvement was pronounced and, in order to speed it up magnesium chloride was prescribed by mouth. Two days later the man developed general malaise with loss of appetite, and the tracheotomy wound had lost its healthy appearance. The magnesium chloride was discontinued and a purge of mild mercurous chloride was given. Forty-eight hours later he again felt comfortable, and the appearance of the mucosa of the larynx and the tracheotomy wound gave the clue to the amount of magnesium chloride that could be tolerated and assimilated by the patient. Fifteen days after the treatment was begun the feeding tube was removed and deglutition returned gradually to normal. One month later the edema had disappeared from the epiglottis and the ulceration of the mucous membrane of the larynx had disappeared. When the tracheotomy tube was removed, the patient could whisper; abduction and adduction were returning slowly. One month and two days from the time the treatment was first started, the patient left the hospital.

Acidosis of Guanidine Intoxication.—Minot and his associates show that guanidine intoxication causes an acidosis due primarily to increased production and defective metabolism of lactic acid. The administration of alkalinizing sodium salts in the treatment of this acidosis is attended by unusual difficulties because of the danger associated with any temporary decrease in the effectiveness of calcium ions in the presence of increased guanidine. Sodium lactate fails to increase the alkali reserve because of the inability of the subject to utilize lactates. Sodium bicarbonate, while at times both dangerous and ineffective if used alone, can be made safe and promptly efficient if calcium medication is combined with its administration. A gradual relief of acidosis results from calcium medication alone or from the intravenous administration of fluid in the form of dextrose solution or physiologic solution of sodium chloride. The latter procedure also improves the condition of the subject by hastening the excretion of guanidine through improved kidney function. The authors have found that the most satisfactory treatment of the acidosis produced by the administration of guanidine is the use of sodium bicarbonate combined with repeated intravenous calcium medication and the injection of liberal amounts of fluids to increase the urinary output. The same form of treatment is recommended for severe acidosis in clinical subjects with hyperguanidemia.

Effect of Alkali on Peptide of Thyroxine from Gastro-Intestinal Tract.—Thompson and his co-workers prepared a peptide of thyroxine containing 48 per cent of iodine, with a nitrogen:iodine ratio of 0.48:1, from a proteolytic digest of desiccated thyroid. This product is insoluble in distilled water but soluble in a dilute solution of sodium hydroxide. When suspended in distilled water and administered by mouth to patients with myxedema, it produced only a slight increase in the basal metabolism, which was about the same as that produced by the oral administration of the monosodium salt of thyroxine in doses which contained the same amounts of iodine, and about one fourth as great as that produced by thyroxine in alkaline solution given intravenously. However, when administered by mouth in an alkaline solution the peptide produced a well marked increase in the basal metabolism, which was nearly four fifths as great as that produced by thyroxine in alkaline solution given intravenously and slightly greater than the increases produced by the oral administration of desiccated thyroid and thyroxine in alkaline solution. The authors' observations were made on three patients who had well marked myxedema. In the second patient the myxedema was spontaneous and in the other two it followed a subtotal thyroidectomy for exophthalmic goiter.

Effect of Exercise on Blood Sugar in Diabetes.—Richardson observed sixty-one diabetic patients by means of a standard form of exercise, in an effort to determine whether they differ in their response to exercise and whether the severity of the diabetes influences the response. The exercise selected consisted of four five-minute periods of work on the ordinary type of rowing machine exerciser. He found that the effect of exercise of the degree and character employed in these experiments, after sixteen hours without food or insulin, varied with the severity of the diabetes as indicated by the fasting blood sugar level. With increase in the fasting blood sugar level from a normal value to about 175 mg. per hundred cubic centimeters of blood, the effect of a half hour of standardized exercise induced a progressively more marked lowering of the blood sugar. With further increase in the fasting blood sugar level from 175 mg. to more than 300 mg., the effect of a half hour of standardized exercise induced a progressively more marked elevation of the blood sugar. In cases of severe diabetes the intravenous injection of 0.1 unit of insulin, which given before a period of rest was without marked effect on the blood sugar, caused, when given immediately before a period of exercise, a recognizable drop in blood sugar. Five times this

dose given intravenously a half hour before the exercise was begun failed to prevent in cases of severe diabetes this rise associated with the exercise. The effect of from 0.5 to 5 units of insulin subcutaneously was not influenced by rest or exercise. Recent intake of food led under certain conditions to a decrease in blood sugar during exercise in two diabetic patients, who, fasting, exhibited a rise of blood sugar during exercise.

Mechanism of Invasiveness of Streptococci.—Dennis and Berberian confirm Menkin's observations of the failure of inflammatory fixation in areas of acute inflammation due to *Streptococcus haemolyticus*. The lack of inflammatory fixation in the presence of streptococci is not due to the passive nature of the streptococcus but may be attributed to the production of fibrinolytic and antifibrinogenic substances, which dissolve the fibrin barrier or prevent its formation, thus maintaining the patency of the lymphatics and capillaries and facilitating the dissemination of the organisms. The production of fibrinolytic or antifibrinogenic substances and the invasiveness of a given strain of streptococcus are correlative. Both substances are relatively thermostable. Fibrinolysin is destroyed if held at 100 C. for one hour. The antifibrinogenic substance is weakened but not destroyed under the same conditions. There is evidence that both substances are antigenic and exhibit some degree of type specificity. The authors discuss the rôle of fibrinolysin and the antifibrinogenic factor in the invasion of the tissues by streptococci.

Minute Hemolytic Streptococci.—Long and Bliss describe the cultural and biochemical characteristics of a group of minute heretofore undescribed beta hemolytic streptococci from human sources and on the basis of these cultural reactions suggest that the organisms may represent new species of the genus streptococcus. It is evident from the study that, while they resemble ordinary beta hemolytic streptococci in many respects, they cannot be classified under any previously described groups of the latter organisms. The individual organisms are smaller than ordinary hemolytic streptococci, and the colonies are much more minute. Their fermentation reactions in the test sugars resemble those described for ordinary hemolytic streptococci of human origin except in three instances in which they conformed to those described for the organisms isolated from stranglers in horses. None of the strains hydrolyzed sodium hippurate nor did they reduce methylene blue milk. The majority of the strains produced a fair amount of acid when grown in 1 per cent dextrose broth. None of the tested strains showed the presence of the fibrinolytic substance. While all strains possess certain of the characteristics of ordinary beta hemolytic streptococci, none of them completely conform to known species of these organisms.

Minute Hemolytic Streptococci in Man.—Long and his associates observed that minute beta hemolytic streptococci occur in normal persons from a third to a half as frequently as ordinary beta hemolytic streptococci. They were rarely isolated from the rhinopharynx of persons suffering from chronic disease. In

acute infection of the respiratory tract other than that due to the ordinary beta hemolytic streptococcus, the incidence of minute streptococci was slightly higher than in normal subjects. In acute streptococcal infections, scarlet fever and acute tonsillitis, for example, the incidence of minute hemolytic streptococci did not vary significantly from the incidence found in normal human beings. Minute beta hemolytic streptococci were found in the throats of thirty-three of forty-two patients having glomerular nephritis and in twenty-five of fifty-nine patients who were suffering from the various manifestations of rheumatic fever. In glomerular nephritis and rheumatic infection the minute beta hemolytic streptococci were isolated from the throats of more patients than were the ordinary beta hemolytic streptococci.

Bacterial Agglutination.—Heidelberger and Kabat describe a method that affords an exact analytic determination of the total amount of agglutinin present in absolute, not relative, terms and should therefore be useful in instances in which accuracy is demanded and scientific, not routine, data are sought. It has yielded evidence of the quantitative correspondence of agglutinin and precipitin and has afforded new data on the mechanism of bacterial agglutination. The method should be useful in determining the agglutinin content of standard serums, with which serums could then be compared by the commonly used relative methods. The authors state that the range of applicability of the method among the nonencapsulated bacteria is yet to be determined. Preliminary tests with a hemolytic streptococcus system were not encouraging, as complete absorption of the antiserums required too large amounts of the heat-killed suspension used. Experiments are being continued with other types of streptococcus suspensions. It was possible to estimate quantitatively the agglutinin content of a serum for different variants of the same organism.

Agglutination Reactions in Rheumatoid Arthritis.—Dawson and his associates made a comparative study of precipitins and agglutinins against Streptococcus haemolyticus in the serums of seventy-one cases of rheumatoid arthritis and in seventy-nine cases of other diseases. The results indicate that there is a close approximation, but not an absolute agreement, in the capacity of rheumatoid arthritis serums to agglutinate strains of Streptococcus haemolyticus and to precipitate various group specific fractions of this organism. With certain exceptions the control serums examined did not show the presence of either agglutinins or precipitins in significantly high dilutions. The authors believe that their observations offer suggestive evidence in favor of the hypothesis that rheumatoid arthritis is associated with infection by Streptococcus haemolyticus.

Neurologic Observations in Mastoiditis.—Nielsen and Courville studied 106 consecutive cases of clinically uncomplicated mastoiditis in an effort to establish what signs and

symptoms may occur without intracranial extension. Each patient was studied from the neurologic standpoint with especial reference to pupils, eyegrounds, headache, nystagmus, reflexes, pain in the distribution of the trigeminal, meningeal signs, aphasia, cerebellar symptoms, perimetric changes, extra-ocular palsies and dementia paralytica. Also focal convulsions, general toxemia, chills and sweats, acuity or chronicity, nausea and vomiting, laterality, age and sex were noted. Pathologic signs and symptoms were observed in the following order of frequency: alteration in deep reflexes, headache (ipsilateral hemi and frontal headache predominating), eyeground changes, pathologic reflexes, chills or severe sweats, pupillary changes, pain in the ipsilateral eye, vomiting or severe nausea, nystagmus, meningeal signs and pain in the ipsilateral jaw. As to laterality among the unilateral cases, forty-eight were left and twenty-eight right. Sex distribution was equal. Aphasia, cerebellar symptoms, extra-ocular palsies, focal convulsions and perimetric changes were not observed.

Effect of Caffeine and Coffee on Blood Pressure.—Horst and her associates gave fourteen men, from 20 to 25 years of age, caffeine or coffee (dosage, 3 or 4 mg. of caffeine per kilogram of body weight) once or twice a week and decaffeinated coffee on the intervening days. In certain studies, bouillon was administered as a control beverage. The blood pressure and the pulse rate after decaffeinated coffee were essentially the same as after bouillon. After coffee or caffeine, the blood pressure and the pulse rate were altered, although the changes were small and often uncertain. One or two hours after the drugs, the blood pressure was usually increased (from 5 to 10 mm. of mercury), the pulse rate decreased (5 per minute) in certain subjects and increased in others. Twenty-five hours after the drugs, the blood pressure was not changed, but the pulse rate was at times increased. Motor function was

changed by coffee or caffeine, the response to single doses being relatively uniform throughout the two months of experimentation. The performance of a simple movement (target test), was usually improved one or two hours after coffee or caffeine but impaired in certain subjects, particularly twenty-five hours after the drugs. Caffeine exerted a sustained, deleterious influence on the performance of an acquired motor skill. Decaffeinated coffee did not affect performance of this skill. In the target test the effect of caffeine or coffee on performance was not apparent later than twenty-five hours after the drugs, but in the acquired motor skill each dose exerted an influence for several days.

Effect of Habitual Use of Coffee on Blood Pressure.

—Horst and her co-workers administered caffeine equivalent to a dose of 3 or 4 mg. per kilogram of body weight or a like quantity of decaffeinated coffee (or bouillon), once daily for periods of from three to eight weeks to seven men from 20 to 25 years of age. During the periods on coffee, the blood pressure was usually higher than that on decaffeinated coffee, the increase being distinct in some subjects and slight or variable in others. The rise in blood pressure seldom exceeded 10 mm. of mercury and was somewhat less in the latter weeks of the periods on coffee. Motor function was changed throughout the periods on coffee. In one motor test (target), improvement in performance reached a maximum in the first two weeks on coffee, then decreased slightly, but was still apparent in the latter weeks (fifth to eighth) on coffee. In another motor test (acquired motor skill) performance was impaired markedly throughout the periods on coffee, the impairment of performance being almost as great in the latter weeks (fourth to seventh) as in the first part of the period. When coffee was withdrawn, the blood pressure returned quickly to the level found after decaffeinated coffee, but performance was impaired in both motor tests during the first week after withdrawal of coffee. During the periods on decaffeinated coffee the blood pressure was not far different from that when bouillon was administered. In the acquired motor skill, performance on decaffeinated coffee was essentially the same as that when bouillon was administered or when no special beverages were taken.

Ureteral Occlusion Following Radium Implantation in Cervix.—Since 1930, Bugbee has nephrectomized six patients following irradiation of the cervix for carcinoma. Two other cases were referred to the urologic department, one presenting

an occlusion of both ureters, the other a unilateral occlusion, in both instances secondary to irradiation of the uterus. Seven of the patients were admitted to the hospital complaining of vaginal bleeding; all but one showed a squamous carcinoma of the cervix on biopsy; all except one were treated with radium, one or more tubes being inserted into the cervical canal for a minimal dosage of 1,787.5 mg. hours and a maximal dosage of 4,857.68 mg. hours. In three cases, needles were inserted also into the cervix; and five patients had received high voltage roentgen therapy. In four cases the carcinoma had extended into the vaginal wall. None of these patients showed evidence of metastasis when first treated. None had urinary symptoms at the time of the first irradiation, and in all but one the urinalyses were negative. The ureteral obstruction was unilateral in seven cases and bilateral in one. In six cases a functionless kidney due to pyonephrosis and secondary to a ureteral occlusion was removed; the time elapsing between the irradiation and the nephrectomy was from five months to nine years. Of the two patients not operated on, the bilateral obstruction occurred in one case one month and in the other one five years after the irradiation. None of the kidneys removed showed metastasis; one was tuberculous when removed but negative at the time of irradiation. In two cases of ureteral occlusion that came to necropsy, carcinoma was found to have extended to or metastasized in the occluded ureter. It is quite possible that in the other cases the growth had extended in a similar manner and that the early breaking down of the tumor tissue after irradiation, with the rapid cicatrization that had resulted, had accounted for the early ureteral occlusion and the establishment of a ureterovaginal fistula in three cases. The author gave smaller doses of radiation than did Dean, which probably accounts for the absence of lesions of the bladder, except in one case, the patient having received radiation elsewhere. In the case in which there was an obstruction of both ureters one month after irradiation, the microscopic sections of the ureters and adjacent tissue showed carcinoma and cicatricial tissue in the ureters and surrounding tissue. He believes that the results obtained by irradiation in the treatment of cervical carcinoma have been such as to warrant its general employment in those cases. The possibility of ureteral occlusion, either unilateral or bilateral, secondary to its use and resulting in the slow destruction of a kidney possibly necessitating nephrectomy, must be considered. In the follow-up examinations, the urinary tract should receive careful attention. Urinary examinations should be made regularly and supplemented by excretory urograms and cystoscopic investigations, when symptoms or physical signs are present that suggest the possibility of ureteral occlusion.

Treatment of Prostatic Hypertrophy.—Kirwin explains nondestructive shrinkage as a heat treatment by high frequency current, a given current density being applied to a measured area of tissue for a definite length of time. The unit of measurement of current density is called a millimil. The depth to which the heat will penetrate during a given period of time may be predetermined. The shrinkage method, as its name implies, withdraws fluid and coagulates albumin, so that the treated tissues are reduced in volume and changed in consistency. The temperature within the tissues is raised to a degree that kills living adenomatous cells but does not injure blood and lymph vessels. The object is to carry the heat treatment beyond the point of tolerance in the unanesthetized patient (in diathermy) but not to the point of tissue destruction, as in coagulation. By coagulation of albumin and evaporation of tissue fluids, the gland will be reduced greatly, without subjecting the most debilitated patient to the chance of surgical shock. The author describes an instrument designed for efficient application of the procedure and cites a series of cases in which the procedure was used.

Relief of Endometrium with Thorium Hydroxide Sol.
—Menees and Miller prepared a colloidal suspension of thorium hydroxide by peptizing it with an appropriate amount of thorium nitrate solution. This was prepared by the precipitation of the hydroxide through addition of dilute ammonium carbonate solution to a dilute solution of thorium nitrate. This gave a flocculent white precipitate, which was allowed to settle, washed, the required amount of thorium nitrate added and then concentrated by boiling to the desired strength. The solution so obtained is opalescent in appearance and thin enough to be drawn through a small cannula with ease. It has a p_n value of approximately 6. It coagulates and adheres to a surface when coming in contact with dilute alkalis or mucus. The film deposited in this manner is sufficiently opaque to the x-rays to give a satisfactory demonstration of the relief of the endometrium. The deposited material does not remain in place but is soon loosened, apparently by secretion from the mucous surface, and expelled. For injection the solution is drawn into a sterile 20 cc. syringe to which is attached a small caliber cannula. The cannula is passed through the cervix into the fundus of the uterus and injection is made slowly, its tip being turned from side to side and it being moved back and forth so that the solution is well distributed over the interior of the cavity, care being taken that there is a free return of fluid round the cannula. After injection, the fundus is massaged a few times with the hand to expel any excess of fluid. The speculum is removed, the tenaculum being left in place. An anteroposterior view is then taken, the Potter-Bucky diaphragm being used. If the shadow is too dense to give good detail, the patient is allowed to get up and walk about for a few minutes. When a satisfactory shadow has been obtained, right and left oblique and postero-anterior views are taken. It is advantageous to use moderate traction on the tenaculum while the postero-anterior view is being taken in order to straighten the uterus as much as possible. The authors state that roentgenograms taken in this manner outline clearly the contour of the uterine cavity; the relief of the mucous membrane produces a latticed appearance as the result of the deposit of the material in the crevices between the folds in thicker layers than on the summit of the folds.

Autogenous Vaccines in Treatment of Nasal Allergy.
—Cox reports nineteen cases treated for nasal allergy and chronic sinus infections in which autogenous vaccines prepared from washed organisms and the diluted broth filtrate from eighteen-hour cultures of the organisms were used. The patients treated included those referred to the laboratory after having undergone long continued treatment in the eye, ear, nose and throat clinic, cases of obscure nasal allergy and cases of bronchial asthma. Of the nineteen patients, fifteen were so improved as to be classed as cured. Two patients with bacterial allergy, although classed as cured, find it necessary to report at intervals for treatment. Four patients were not benefited by vaccine treatment. During the past nine months the predominating organisms occurring in the nose and throat cultures of patients being

given routine treatment have been *Streptococcus haemolyticus*, *Streptococcus viridans*, *Staphylococcus aureus* and *Staphylococcus albus*. There was a marked seasonal variation. Throughout the fall the *Streptococcus viridans* group predominated, during the spring the *Streptococcus haemolyticus* group. The author concludes that treatment by means of autogenous vaccine has benefited the majority of patients referred to the laboratory during the past two years suffering from chronic sinus infections, nasal allergy and associated asthma of the bronchial type.

Use of Sodium Amytal in Psychiatric Patients.—Smith and Schwartz gave sodium amytal orally and intravenously to six stuporous and uncommunicative psychiatric patients with whom contact could not be established. It was found that in all but one case oral administration although increased to a total dose of from 12 to 18 grains (0.8 to 1.2 Gm.) in twenty-four hours did not produce adequate contact. Under the dosage used there was little or no spontaneous speech by the patients, but in all but one case there was a response to questions. The period of response varied with the patient as the initial doses were uniform. The intravenous method produced a better result than the oral, although one patient showed an adequate response to the latter. Continued oral administration following intravenous injection did not result in producing as good contact as obtained immediately after intravenous dosage. The use of a standardized dose does not give the best results. The dosage should be varied in accordance with the individual tolerance.

Simplified Cough-Plate Method for Early Diagnosis of Whooping Cough. I. S. Barksdale and F. P. Simpson, Greenville, S. C.—p. 943.

Method for Diagnosis of Whooping Cough.—Because of the possible inhibiting effect of glycerin, Barksdale and Simpson left it out of their culture mediums for plating *Bacillus pertussis*. Ordinary nutrient agar was used, enriched with potato or turnip extract. The proportion is 10 cc. of nutrient agar to 5 cc. of the extract. The nutrient agar has 1 liter of water, 3 Gm. of beef extract, 5 Gm. of peptone and 15 Gm. of agar adjusted to pH 6.7. For the potato extract, three or four medium sized Irish potatoes are peeled and cooked in about a quart of water for half an hour. This is filtered through cotton and autoclaved, then added to the nutrient agar. The plate is held about 6 inches from the patient's mouth and the child is allowed to cough directly on the congealed agar in the dish. The plate is then placed in the incubator at the usual temperature, bottom up, to minimize evaporation. At the end of twenty-four hours the typical small, nearly transparent colonies of the Bordet-Gengou bacillus are seen. A platinum loopful of water is placed on a clean glass slide in two places. The organisms are transferred from the most typical colonies to the droplet of water and thoroughly emulsified. The specimen is dried, fixed in flame, stained in 1:5,000 bismuth-violet for three minutes and examined under the microscope with the oil immersion objective. The Bordet-Gengou bacillus is stained a deep purple with bismuth-violet and appears as a short, stubby bacillus in sizes varying from 2.5 to 5 microns.

Carbon Dioxide Hyperventilation and Aeration of Lungs.—To determine whether the treatment of patients after operation with carbon dioxide inhalation has any effect in preventing or even diminishing the crippling of the respiratory

system that occurs following laparotomy, Beecher studied twenty-two patients who received carbon dioxide treatment after laparotomy and twenty-eight used as controls, who received no treatment. Of the treated patients there were eight men and fourteen women; of the controls, ten men and eighteen women. Of the treated patients, eleven underwent upper abdominal laparotomies and eleven operations on the lower part of the abdomen or herniorrhaphies, while in the control group eleven were submitted to operations on the upper and seventeen to operations on the lower part of the abdomen. In all cases each treatment produced marked hyperpnea and was continued as long as the patient could endure it. In every case there is a close relation between the treated and the control curve. In no case has the divergence of the two curves exceeded the limit of experimental error. In the cases studied, carbon dioxide therapy following laparotomy had no effect in preventing the crippling of the respiratory system.

Lipid Composition of Leukocytes During Pregnancy, Lactation and Puerperium.—Boyd studied, under controlled conditions of diet and exercise, the lipid content and distribution in the white blood cells of eleven women at or near the termination of pregnancy, during lactation and the puerperium. It was found that age and parity did not affect the level of lipids in the leukocytes. Before parturition the white blood cells have a wide range of lipid values though, on the average, cholesterol ester and neutral fat are low in amount and the total lipid content is reduced by about one fourth from the mean levels in nonpregnant women. Following parturition there is no change in the lipid composition of the leukocytes of the blood until the third to the seventh day. Then there occurs a rise in total lipid due to increases in phospholipid, free cholesterol and neutral fat. These high values appear to return to normal, beginning about three weeks after delivery. Cholesterol ester is present in small amounts throughout. On the basis of the current theory the author interprets these results as indicating an increased activity on the part of the white blood cells during the first two to three weeks of the puerperium.

Carcinoma of the Colon.—In the operative procedures that MacGuire discusses, not once has he used clamps or severed the colon by cautery as is done in all forms of anastomosis. Nor does he suture the wall of the colon to the parietal wall of the peritoneum. In his opinion the mortality of surgery of the colon will remain high if surgeons in general adopt any of the so-called aseptic technic operative procedures. He believes that the term is a misnomer, as every time clamps are applied across the lumen of the colon the wall is traumatized so severely that hordes of microscopic or ultramicroscopic bacteria are spilled into the peritoneal cavity. So infection and tension are the chief adverse factors of all colon operative procedures to date. In the operation that he describes, the mortality should be so much lower that its lack of danger will appeal to the careful surgeon. In all cases of cancer of the colon a preliminary cecostomy is made through the McBurney gridiron incision. The patient is sent home for a rest of two months before the radical abdominoperineal excision is performed. On reentrance to the hospital, a complete check up is again made. The administration of transfusions—dextrose, sodium chloride—and the application of an indwelling catheter are ordered. A median or left incision is made and the mesentery of the left colon is resected from a point above the growth down through the peritoneal reflection, the gland-bearing area being excised. The abdomen is then closed temporarily. The patient is placed in the lithotomy position for the perineal resection. The perineal incision is made preferably with a cautery and continued until sufficient rectum extrudes so that a sterile rubber glove can cover the lower intestine completely. After dissection has been done up to the peritoneal reflection, the abdomen is reentered, the peritoneal reflection is dissected and the entire loop is carried outside the abdomen. Before this is done, a separate incision is made in the left rectus muscle and the entire freed intestine is carried through this aperture for the purpose of fashioning a single barrel colostomy. The peritoneal reflection and the incision in the abdomen are closed. The cut edges of the sigmoid mesentery are sutured to the left parietal peritoneum to prevent herniation. The extraneous intestine is double clamped a few inches from the colostomy opening and severed with a cautery,

which completes the single barrel colostomy. In cases of tumor of the left colon in which the growth is resectable, a modified Mikulicz and Paul operation is preferable. The preliminary colostomy operation is performed and the patient is sent home to recuperate. Two months later, the patient reenters the hospital and a complete check up is again made. The usual incision is made on the left side of the median line and the growth is surrounded with laparotomy pads. It should be long enough to permit the growth to be drawn well outside the abdomen and the two barrels of the colon approximated for a distance of from $2\frac{1}{2}$ to 3 inches. The approximation is made by sutures through the cut edges of the mesentery. In dealing with carcinoma of the left part of the transverse colon and the left colon and sigmoid, one can draw more colon out of the abdomen if the phrenicocolic ligament is severed fairly high up. In the newer Paul-Mikulicz type of operation, no sutures are used to approximate the parietal peritoneum with the colon proper. If necessary, however, the parietal peritoneum can be sutured to the cut edges of the mesentery. At the end of seventy-two hours, the tumorous mass can be resected with a cautery and the usual follow-up procedures of the Paul-Mikulicz operation can be accomplished without any undue haste. By means of a continuous suction apparatus the wound can be kept clear of debris. With the preliminary cecostomy and suction, faster healing is accomplished. This same operative procedure can be used for carcinomas of the transverse colon.

Drainage of Common Bile Duct for Gallstones.—From a study of forty-two cases in which the common duct was drained through the stump of the cystic duct, Zinninger and McCandless conclude that this should be the method of choice when drainage of the duct is necessary. It allows complete and accurate suture of the exploratory incision, which predisposes to early, firm healing of the incision with minimal scarring. It provides a long narrow channel for the drainage tube, which ordinarily remains water tight until it is time to remove the tube. Removal of the tube causes little damage or disturbance to the common duct, and drainage of the bile from the wound after the removal of the tube is of short duration. The method therefore reduces the total loss of bile and shortens materially the duration of the convalescence.

Coronary Endarteritis in Acute Rheumatism.—Fraser presents four cases of acute rheumatism, in which the condition found in the coronary arteries illustrates the occurrence of an endarteritis which is specific in type, the intima undergoing a diffuse inflammatory reaction which reduplicates the histologic features of the Aschoff nodule. The initial change is an intimal cell proliferation, which may lead to fibrotic thickening or simple intimal hypertrophy. This is followed by fibrinous exudation or necrosis, mobile cell infiltration and the appearance of those basophil giant and multinucleated cells which denote the presence of the virus of acute rheumatism. Usually there is marked degeneration of the internal elastic lamina and of any other elastic layers that may have formed in the intima. Unless complete obliteration of the lumen occurs, the vascular endothelium remains intact and thrombosis does not take place. An interesting feature is the occasional isolation of small luminal spaces or even the complete partition of the lumen, which in the later stages leads to the simulation of intimal vascularization or thrombus canalization. Sometimes the intimal cells, in keeping with their mesenchymal origin, reproduce layers of what appear to be smooth muscle cells round these luminal spaces, thus giving them the appearance of thick-walled vessels. A common accompaniment of this endarteritis is a perivascular inflammation, which may be of the Aschoff nodule type or consist of a more diffuse inflammatory reaction with numerous mobile cells, isolated Aschoff cells and many distended blood vessels. Communication between the lumen of the affected segment of the vessel and these perivascular blood vessels is established through the formation of new capillary channels, which pass through the media. The media may remain unchanged or it may be involved through spread of the infection either from the intimal or the adventitial side or from both. As a result, medial muscle cells disappear and are replaced by fibrous tissue. Both coronary arteries may be affected and at any part of their course, but the condition is more commonly found in the smaller branches of the left coronary artery. The vascular lesions observed in these cases show that in acute rheumatism the coronary arteries may be infected not only from the outside, the virus gaining access by way of the perivascular lymphatics, but also from the inside, the virus passing directly into the wall from the lumen.

Sedimentation Rate in Rheumatic Carditis.—Perry performed 1,043 estimations of the sedimentation rate on 167 children suffering from rheumatic heart disease. The high sedimentation rate found in acute rheumatism is in no way a specific reaction, since many other acute and chronic infections show a similar change. The absence of any constantly high sedimentation rate in chorea uncomplicated by carditis is puzzling. Payne has suggested that this observation is due to the fact that the cases with chorea have not come under observation until late in the disease when the chorea is a residual phenomenon. The two patients who developed chorea during convalescence from an attack of rheumatism with no change in the sedimentation rate suggest that this is not the true explanation. It was hoped that the sedimentation rate might provide a clue to those smoldering cases which show no gross clinical evidence of activity but deteriorate rapidly on being set free from restraint and treatment. In some cases this is so, and it is clear from this study that any rheumatic child showing a persistently abnormal sedimentation rate should be regarded as having active disease unless some other cause for the change in the blood can be found. A single normal sedimentation rate does not exclude the possibility of a smolder-

ing activity, but if persistently low it is unlikely that the rheumatic process is active. In sixteen cases, subcutaneous nodules developed at the end or late in the attack: in nine they appeared when the sedimentation rates had fallen to between 10 and 20; in six the sedimentation rate was more than 20 at the time the nodules first appeared, and the remaining case was not seen until the nodules appeared, at which time the sedimentation rate was 6. Fresh nodules did not appear after the sedimentation rate had fallen below 10.

Nephritis in Infancy.—Rennie reports ten cases of acute nephritis in infants less than 18 months of age. The disease was characterized by obstinate edema and a reduction of serum proteins in every case. Seven of the cases were fatal, death being due in five or possibly six either to pneumonia or to enteritis. In one case, death was due to cellulitis. The other three patients made complete recoveries, in one without any special form of treatment. High protein diet was used in one and ammonium chloride in another, but there was no evidence that recovery was due to these therapeutic measures. There was no evidence that the nephritis was the result of a syphilitic infection. The edema was ascribed in every case to a fall in the serum protein with consequent reduction in the oncotic pressure. This was a constant observation and the condition differs in this respect from acute nephritis as seen in older children, in which a fall in oncotic pressure below edema level occurred in only 14 per cent. Attempts at treatment should be directed toward causing a rise in the serum proteins as the cure is coincident with their return to normal. Spontaneous cure as in older children accounted for all the recoveries.

Treatment of Rheumatism by Streptococcus Antitoxin.

—Eason and Thomson present a study of twelve cases of acute rheumatism that were treated by means of streptococcus antitoxin. The antitoxin used was concentrated streptococcus antitoxin (scarlatina). The dosage varied from 30 to 90 cc., given intravenously in two or three doses. All patients were tested for sensitiveness to the antitoxin, but none was detected. As a control group, twenty-seven consecutive cases were used who had received treatment by means of salicylates. The results show that the average time elapsing between the administration of the antitoxin and the patient's discharge from hospital was 58.5 days. In the case of the control group treated by means of salicylates, the average stay in the hospital was 43.2 days. In comparing these figures, it must be borne in mind that in treatment by antitoxin there is almost invariably a febrile reaction at the time of the appearance of the rash, which inevitably results in a slight prolongation of the period of treatment. The antitoxin cases were also kept in the hospital for lengthy observation in view of the experimental nature of the treatment. In a number of cases throat swabs were examined for the presence or absence of hemolytic streptococci and the skin reactions to intradermal injections of extracts of hemolytic streptococci were investigated. No correlation could be shown to exist between the skin reactions to such extracts and the course of the disease before or after the administration of the antitoxin. A study of the clinical records of the cases showed that in the series treated by antitoxin the results could be considered good in nine cases and moderate in three; while in the series treated by salicylates the results were good in fourteen cases and moderate in three. Ten cases showed no improvement after prolonged treatment.

Coronary T Wave in Electrocardiograms in Pericarditis.—Peel describes six cases in which pericarditis was associated with displacement of the RT segment of the electro-

cardiogram similar to that which occurs in coronary thrombosis. In forty-eight cases of pericarditis, some abnormality of the RT- or T segment was found in twenty-nine (60 per cent), though in only seventeen (35 per cent) can other possible causes be excluded. In nineteen (40 per cent) the RT and T segments were normal, though in one third of them other electrocardiographic evidence of myocarditis was obtained. The evidence points to myocarditis rather than pericardial effusion as the cause of the RT and T wave changes, although experimental work in the literature shows that they can be produced by raising the intrapericardial pressure. In a proportion of cases, though not in all, pericardial effusion causes diminished voltage of QRS.

Sporadic *Salmonella* Infections.—Smith discusses the serologic characteristics of a heretofore undescribed *Salmonella* organism and also one (*Salmonella* potsdam) which has not been described previously as occurring in Scotland. The organism was isolated from a case of acute enteritis occurring in a child of 11 months. A non-lactose fermenting organism was obtained from the feces. The organism produced acid and gas in twenty-four hours in mediums containing dextrose, mannite, dulcitol, xylose, arabinose and rhamnose but failed to ferment inositol, even after an incubation period of ten days. It failed to produce indole in peptone water but produced blackening on lead acetate agar and an acid to alkaline reaction in litmus milk. The organism was apparently in the group phase when first isolated, but after plating and selection of single colonies, no difficulty was found in obtaining a specific phase form; i. e., one that would not agglutinate with the group serum for *Salmonella* europaei-suispestifer. The specific phase H antigen agglutinated to the full titer of the specific *Salmonella* aertrycke serum and absorbed the agglutinins without difficulty from that serum. When the organism was tested against the O antigen antiserum for the paratyphoid B group, it did not agglutinate with this serum or absorb the agglutinins from it. The cultural characteristics, salt and thermo-agglutination tests did not show evidence of any rough variation. Agglutination tests and agglutinin absorption tests with other O serums failed to agglutinate the organism, and the agglutinins were not absorbed by it. An account is given of sporadic *Salmonella* infections. The investigation has shown that the most frequent cause of such infections are *Salmonella* types aertrycke, thompson, dublin, enteritidis and europaei-suispestifer. It has been

found that the dublin and suipestifer types are definitely more tissue invasive than the other types. Septicemia and meningitis have been associated with infections due to *Salmonella dublin*, and septicemia in cases infected with *Salmonella suipestifer*.

Antigenic Relationship Between *Brucella* and *Pasteurella*, *Pfeifferella* and *Proteus* Organisms.—The experiments of Wilson lend no support to the suggestion put forward by various workers of the existence of an antigenic relationship between *Brucella* strains and strains of *Pfeifferella*, *Pasteurella* and *Proteus* X. The evidence on which such an assumed relationship is based is wholly insufficient to bear the weight of the conclusions drawn from it. The evidence accumulated in the last few years points strongly in favor of the existence of a high degree of antigenic specificity in most groups of organisms examined. In the interpretation, however, of routine agglutination tests made on human or animal serums, it is essential to know the normal level and variation of agglutinins, either naturally present or acquired through latent or overt infection, to the particular organism under consideration. It is neither generally nor sufficiently recognized that the level of "normal" agglutination for a given species depends directly on the sensitiveness of the strain used in estimating it. In somatic O agglutination, with which the author's discussion is concerned mainly, the difference in sensitiveness of different strains of the same species is considerable. One of the best known examples is that of strain 901 of *Bacterium typhosum*, whose sensitivity to O agglutinins is from five to ten times that of the common strains of this organism (Felix, 1929). Provided that due precautions are taken to ascertain the normal level of agglutinins in a given host and that antigenically smooth strains are used, there is every reason to believe that the occurrence of agglutinins in a titer above the normal range of variation is due to infection—latent, active or past—with the specific organism in question or in a few instances with an organism, usually of the same genus, sharing a similar antigen.

Barbiturates in Epilepsy.—Handley shows that an epileptic patient may receive temporary benefit from any new form of treatment. When this ceases, an impression is obtained that tolerance is established; but this is not true tolerance. The real explanation of this temporary improvement is found in the mental attitude of the patient himself, who responds, but only for a time, to any form of treatment. After an exhaustive test, it was shown that phenobarbitonum solubile (B. P.) is the best drug for general use in an institution. Phenobarbitone reduces greatly the incidence of "jumps," serial epilepsy, prolonged clonic convulsions and status epilepticus; but, with the exception of the first, once these conditions have begun they are not benefited by the drug, unless it is given in large soporific doses. In spite of warnings against prolonged medication, patients are reported who have taken daily therapeutic doses for periods up to twelve years. No sign of mental deterioration is produced, and many are improved markedly. Although it is the custom when withdrawing the drug to do so gradually, the author's practice of sudden complete withdrawal has never been accompanied by any unpleasant symptoms. The evidence that he has obtained supports strongly the opinion of French and German authorities, who say that no craving is established. An idiosyncrasy to phenobarbitone may occur, but the author has found that it never has occurred with the soluble alkaline drug. Most people agree that, even if idiosyncrasy occurs, ample warning is given. Emphasis is laid on the importance of suitable environment if epilepsy is to be treated successfully. The possibility of danger in phenobarbitone treatment has been exaggerated greatly and the severity of toxic symptoms magnified. The drug has undoubtedly diminished the incidence of serious sequels, and a patient becomes brighter and more equable when under its influence.

Operations for Prolapse.—Bonney postulates that prolapse is a purely vaginal phenomenon, in the causation of which the uterus does not play any direct part but acts more or less as a deterrent. The vagina, in its relation to the peritoneal cavity, is in exactly the same position as the in-turned finger of a rubber glove. In both cases there is a culdesac intruding into a closed cavity, the pressure within which is liable to a sudden rise. The intra-abdominal pressure depends partly on the gas pressure in the intestine, the muscular contraction of the abdominal walls and the weight of the movable viscera. Of these three components the first acts equally in all directions, the second more often toward the pelvis than toward the diaphragm, while the third, being dependent on gravity, acts downward, and as a result the walls of the lower part of the peritoneal cavity are in the standing, sitting and squatting postures more exposed to a stretching force than those of the upper part. The author discusses the mechanical considerations, the supporting mechanism of the vagina, the effect of the intra-abdominal pressure, the supporting mechanism of the uterus, the increase in the caliber of the lumen of the vagina without a proportional increase in the thickness or strength of its wall, the yielding of the attachments of the wall of the vagina to the abdominal walls, the axis of effect of the intra-abdominal pressure and the position of the initial bulge, from which he concludes that: 1. The intra-abdominal pressure when it rises above atmospheric pressure tends to turn the vagina inside out. 2. This tendency is countered by a mechanism made up of several factors. 3. Prolapse is due to the failure of this mechanism, either in whole or in part. 4. There are several forms of prolapse. 5. The form depends on which part of the sustentacular mechanism has failed. 6. No operative treatment is ideal that does not take into account and rectify or abrogate the factors responsible for the particular deformity and, therefore, no one procedure is a panacea for all cases.

Endometriosis as Manifestation of Ovarian Dysfunction.—Jeffcoate and Potter maintain that the development of endometriomas, irrespective of the primary source of the endometrial elements, is due to an excessive production of estrogenic substance by the ovaries. In a clinical and pathologic study of 111 cases of endometriosis the presence of follicular overactivity is demonstrated in the majority. Endometriosis is regarded as being analogous in many respects to hyperplasia of the uterine mucosa. It is suggested that the same ovarian conditions give rise to the frequently associated overgrowth of fibromuscular tissue. It is claimed that this theory explains more adequately than does any other all the known clinical and pathologic features of the disease.

New Method of Examination—Cystodiaphanoscopy.—Klaffen outlines a method (cystodiaphanoscopy) which utilizes the bladder light for visualizing the contents of transparent ovarian cysts and accumulations of fluid in the abdominal cavity. The method is based on the simple laws of light transmission. The author uses a cystodiaphanoscope composed of four lamps attached to the inner end of a metal rod, which, perpendicularly mobile, serves at the same time as an obturator. These lamps are placed in a tube of 24 Charrière thickness and 20 cm. in length. The extremity of the foremost lamp is strengthened and closes the opening of the tube to the inner side, and 7 cm. from the inner extremity of the tube there is a mark showing when the urethral canal has been passed and the extremity of the tube has entered the bladder. Now the metal rod has to

be pushed forward and the lamps are, one after the other, passed into the cavity of the bladder. Signs on the other end of the obturator make it possible to know the number of lamps already in the bladder. If a dry battery is used, it is provided with a control lamp to show whether the lamps are lighted. The instrument is introduced with precaution into the bladder, after which the lamps are introduced successively, in the number required by the occasion. In removing the apparatus it is so fixed as to avoid every motion, the forefinger is applied to the end of the tube near the notch in its outer end, while the other fingers retract the lamps, one after the other, into the tube. The strengthened foremost lamp closes the inner aperture and covers the border of the tube. By the aid of the cystodiaphanoscope constructed on these principles the author was enabled to examine women with rather fat abdominal walls and to state exactly the facts discovered with the simple cystoscopic lamp. Up to now the degree of translucency of a cyst had to be judged by comparing the intensity of the bladder light with the tumor. The author claims that actually one can judge not only by this comparison of the intensity of translucency of a tumor but also by the number of lamps introduced into the bladder. The light of the bladder in the dark chamber is due to reflection from the vesical mucosa. The effect of the transvesical diaphanoscope permits a conclusion to be drawn about the contents of cystic ovarian tumors, which flash up in case of a clear serous condition of the contents and give passage to a more or less dimmed light in case of pseudomucinous contents of the cyst, according to the grade of admixture of the pseudomucin.

Deficient Acclimatization to Low Oxygen Pressure.—Barcroft and his associates observed a person in good health in a chamber at a reduced partial pressure of oxygen for more than five days. The pressures varied from 116 mm. on the first day to 75 mm. The degree of acclimatization obtained was poor as compared with what has been observed on mountains, the alveolar oxygen pressure falling to about 30 mm. and the carbon dioxide pressure remaining above 28 mm. The figures for the total metabolism fell also. The oxygen dissociation curve at 40 mm. of carbon dioxide pressure and even at the pressure in the body was shifted considerably to the right. The arterial blood obtained by puncture at the time of coming out of the chamber was not more than 65 per cent saturated with oxygen and may have been somewhat less. The subject was intensely cyanosed and in an indifferent mental condition. For some days after the experiment he became unduly hyperpneic on exercise and was appreciably hysterical.

Susceptibility of Mice to Viruses of Influenza.—The evidence of Andrewes and his associates that mice are susceptible to the viruses of human and swine influenza rests on the following facts: 1. Virus of ferret origin regularly produces in mice lesions of the lung not unlike some of those encountered in influenzal pneumonia in man. 2. After several passages through mice, the virus still produces the characteristic disease in the ferret. 3. Cultures of the lungs of infected mice on ordinary mediums are often sterile and do not in any case tend to yield growths of any particular organism. 4. Filtrates of infected mouse lungs through membranes having an average pore size of 0.6 micron are infectious for other mice. This indicates, according to Elford's (1933) calculations, that the diameter of the virus is less than 0.3 micron. 5. The two viruses when isolated from mice are neutralized by the corresponding serums prepared in other animals. 6. The swine influenzal infection in mice is like that in the ferret and unlike that in the pig: the virus alone produces a severe and perhaps fatal disease, no concomitant bacteria being necessary.

Determination of Hydrogen Ion Concentration.—Symons describes a simple colorimetric method for p_H determination that eliminates the use of standard buffer solutions or permanent standards of any sort. A suitable indicator is selected, after the approximate p_H of the unknown is determined, if necessary, e. g., by means of the universal indicator or by trial with various indicators. This indicator is diluted from stock strength and its reaction is adjusted. Six exactly similar tubes are set up in two rows of three each in a comparator block having three rows of holes placed exactly behind each other. If compensation for the color or turbidity of the unknown is unnecessary, two rows of two each are used. Into one tube 5 cc. of the unknown is pipetted (suitably diluted if necessary) and behind it the water blank is placed; into each of the other two tubes 5 cc. of water is pipetted, the one being rendered acid and the other alkaline, with the quantity and type of acid or alkali respectively necessary. To the unknown the given quantity of indicator is added (usually 10 drops, or 0.5 cc., to each 5 cc. of unknown). The same amount of

indicator is distributed between the two tubes, one acidified, the other alkalinized, so that the composite color finally produced matches in tint and intensity that of the unknown. The ratio of acidified to alkalinized dye required to produce the color is determined. From this ratio the p_H is determined by use of the equation. The author finds that 6 drops of indicator in the acid form and 4 in the alkaline form give a composite color which matches in tint and intensity that of the unknown, which contains the same number of drops of indicator; viz., 10. By reference to Gillespie's table, he finds that this drop ratio corresponds to p_H 7.5. As it is a ratio that is being determined, the actual concentration of indicator is not of great importance, provided the sum of the amounts in the two standard tubes equals the amount in the unknown. The results compare favorably with those obtained by standard methods.

Fetal Erythroblastoses.—Two rare conditions affecting the fetus and the new-born are discussed by Péhu and his co-workers. The first is generalized fetal edema due to blood dyscrasia and the second grave familial icterus of the new-born. They report one case involving an anasarca in a still-born fetus of five months, without malformations but with signs of blood dyscrasia, more exactly determined as erythroblastosis. They also describe the necropsy on a boy dying on the fourth day after birth with a marked icterus. They believe with von Gierke in the existence of fetal blood diseases of which the clinical expression is not identical but the cause lies in a profound disorder of hematopoiesis. The clinical response may be generalized fetal edema, grave familial icterus, acute erythrocyte anemia of the new-born, and the acute congenital leukemias. In all probability in these diseases there exists a profound disorder of blood morphogenesis, the development of which operates in an abnormal sense. Prognosis must be reserved in those born alive. If the diagnosis is made certain in the first two days of life, blood transfusions should be given. The authors suggest from 20 to 40 cc. of the mother's blood or that of a universal donor, given intramuscularly. The injections should be repeated daily for one or two weeks. Some successes have been obtained and some long survivals have been observed.

Study of Aleukemia.—Merklen and his collaborators describe a fatal case in which there was true and complete absence of white blood corpuscles. A woman, aged 20, was a worker in a factory where she received a chronic intoxication from the fumes of benzene. The resulting absence of lymphocytes was as complete as that of the granulocytes. The only type of white corpuscles that could be found in the blood were some histiocytic elements, and these did not appear until after contraction of the spleen. The condition terminated with a fatal staphylococcal septicemia. Clinically the aleukemia was associated with thrombopenia with purpura and hemorrhages, with anemia of almost hypoplastic character, and with cutaneous

and visceral necroses. Anatomically the necropsy showed complete absence or rarity of granulocytes in the osseous medulla, similar rarity in the spleen and glands, relative persistence of formation of white cells of the reticulo-endothelial system (but with these not pushed into the circulation), and a scarcity of megacaryocytes and erythroblasts, which explains the purpura and anemia.

Calcinosis of Childhood.—A case of calcinosis developing for about nine years is described by Turpin and his associates. The disease began at the age of 5 following an acute toxic infectious process, which suggested the idea of a dermatomyositis. It involved the muscular aponeuroses and hypoderm and deserved the name of aponeurocellulitis. The acute phase passed, leaving a collagenic fibrosclerotic cellulo-aponeurotic tissue favorable for the precipitation of calcareous salts. The neighborhood of the zones of hemorrhagic infiltration undoubtedly initiated the osteogenic process. By its first phase of acute edema and its second of sclerosis, this calcification shows many similarities to scleroderma complicated by secondary calcification. In this case there was, however, no scleroderma. At present the mechanism is uncertain, but the authors believe that study of the acute phase of generalized edematous scleroderma of infancy, of dermatomyositis, of ossifying polymyositis and of their visceral alterations, especially endocrine, will eventually serve to clarify the cause of these secondary calcinosis and to say in what measure each is an autonomic disorder.

*Role of Iodine in Pathogenesis of Diseases of Thyroid. L. Scheffer.—p. 969.

*Demonstration of Occult Blood in Stool. C. Hablützel.—p. 971.

Treatment of Primary and Secondary Syphilis.—Ramel shows that at present the system of three courses of treatment with arsenic and bismuth compounds according to the technic of E. Hoffmann constitutes for the general practitioner the method of choice in the treatment of primary and secondary syphilis, on the condition that the prescribed intervals between the series are adhered to. Particularly between the first and second course the interval should be a period of from four to six weeks. Serologic control examinations of the blood should be made at the beginning and end of each course of treatment. The serologic reactions at the end of the first and at the beginning of the second series of injections are of especial significance for the prognosis. The patient with primary and secondary syphilis, who has undergone the three courses of the anti-syphilitic combination therapy with success, presents a negative serologic reaction of the blood from the end of the first series of treatments and does not present other clinical signs of syphilis. In these patients further treatments may be dispensed with, but they should remain under medical control to the end of the third year following the infection. The cure of the syphilitic infection is controlled by a reactivation at the end of the third year, and this is followed six months later by a spinal puncture. In case of a negative result of the latter, the marriage of the patient may be permitted.

Iodine and Diseases of Thyroid.—Scheffer shows that in the present status of experimental research it may be asserted that goiter is not caused by a deficiency in the intake of iodine. He admits that the occurrence of iodine in nature (earth, air, water) is low in regions where goiter is endemic, but he maintains that this deficiency in the external iodine is not the cause but only the indicator of goiter. The disturbance in the internal iodine metabolism, however, must be brought into relationship with the disorders of the thyroid.

Demonstration of Occult Blood in Stool.—Hablützel calls attention to the sources of error involved in the benzidine test. He experimented with various foods and on the basis of these studies he reaches the conclusion that patients with gastric and intestinal disturbances, whose stools are to be examined with the benzidine test, must adhere to a special diet

without meat, meat extract, raw vegetables or raw milk. It is also important to have the benzidine solution freshly prepared and to use it within five minutes of its preparation.

Presence of Globin in Cerebrospinal Fluid.—Emiliani and Simili studied the cerebrospinal fluid of a number of patients presenting meningeal and cerebral hemorrhages, hemiplegia, tumors and compression of the medulla oblongata, syphilitic diseases of the nervous system, meningitis and other diseases. The authors found that, when the amount of blood in cloudy cerebrospinal fluid is conspicuous, a notable amount of globin is present. They maintain, however, that, if the amount of blood is minimal, the globin is present only to slight degree. Of fifty-five cerebrospinal fluids examined, twenty-three were cloudy, sixteen clear, two almost clear and fourteen weakly xanthochromous. The reaction of Meyer was negative in eighteen specimens of cerebrospinal fluid, doubtful in two, weakly positive in twenty-two and positive in thirteen. The authors do not believe that slight traces of globin in cerebrospinal fluid have any diagnostic value. To be of value, the globin must be in evidence and the reaction of Meyer must be more than slightly positive. Since the cerebrospinal fluid is believed to be the secretion of the choroid plexus of the ventricles, the authors deem it possible that the slight traces of globin found in all cerebrospinal fluids may constitute the protein complex that distinguishes them under normal conditions. The pathologic amount of albumin as demonstrated by common methods of estimation (such as that of Brandberg-Pfäundler) indicates more than the percentage of global albumin. It also comprises, according to cases, a more or less increased amount of globin. The presence of globin in the fluid has great diagnostic value, in the sense of indicating a hemorrhage, even a remote one, provided it is found in a fairly high percentage. The authors conclude that minute amounts of globin are a constituent of the normal protein composition of the cerebrospinal fluid.

Cod Liver Oil Treatment of Osteomyelitis.—Löhr reports twenty-four cases of acute osteomyelitis of the long bones treated with cod liver oil and a plaster cast. The field of operation was rendered bloodless and a long incision was made over the tender part of the bone. The periosteum was split and pus evacuated. He found it seldom necessary to drill the bone. The wound was filled with cod liver oil, and the skin incision was loosely closed with interrupted sutures. A circular plaster cast was applied. In the next few days a profuse discharge of an emulsion of pus and oil took place. The behavior of the wound could be judged from the temperature curve, the appearance of the tongue, the appetite and the sleep. The cast was removed at the end of the second or the third week, at which time roentgen examination gave an accurate idea of the extent of the involvement. The patient at this stage was submitted to a second operation, in the course of which sequestrums were removed and the bone cavity was filled with cod liver oil. The author later became convinced that the second operation could be dispensed with in a high

percentage of the cases. Of the twenty-four cases, six belonged to the most severe type not amenable to any local treatment and ended fatally. Of the remaining eighteen, the temperature fell promptly in seventeen. In one the temperature remained elevated and a more radical operation was repeated at the end of two weeks. All eighteen patients were discharged as cured. The convalescence was smooth and painless. The author believes that with this method a high percentage of cases of acute osteomyelitis can be definitely cured and thus prevented from passing into the stage of chronic osteomyelitis. The treatment of chronic osteomyelitis differed only in a more radical removal of the involved bone. The resulting frequently enormous cavity was filled with cod liver oil and a plaster cast was applied. The principle of the treatment is not to disturb the tissues. The use of disinfectants, drains, gauzes and frequent dressings is entirely omitted. The convalescence is thus rendered painless and the general outlook with regard to the ultimate cure is brighter. Of twenty-six patients with chronic osteomyelitis given the treatment, one died of embolism, three were not cured, and twenty-two were completely cured and discharged without fistulas.

Operative Treatment of Congenital Bronchiectasis.—Sauerbruch points out that congenital bronchiectasis, though little appreciated by pediatricians, is not an infrequent clinical entity. He believes that fully 80 per cent of bronchiectases of childhood limited to one lobe are of congenital origin. As a proof of his contention the author points out that there were no pleural adhesions or inflammatory pulmonary alterations in the fifty-eight lobes resected by him, the alterations consisting of widening of the bronchi and thickening of the pulmonary tissue. The next proof is furnished by the histories of these cases. They did not exhibit a tendency to colds, nor did the bronchiectasis develop as an immediate sequel to influenzal or whooping cough pneumonia. It is likewise noteworthy that the lung is frequently the seat of congenital malformations, such as cysts of the bronchi or of the pulmonary tissue. The left lower lobe is the seat of congenital bronchiectasis in the great majority of cases. The author raises the question of whether local congenital malformations capable of leading to so grave a condition as bronchiectasis had not better be subjected to a radical removal. That is possible only through the removal of the entire lobe. The author's method for the removal of a lobe is carried out in two or more stages. Two or three ribs are removed and a filling is placed against the pleura. After a number of weeks, when adhesions have formed, it becomes possible to remove the lobe without infecting the pleural cavity and without retraction of the bronchial stumps. The author performed fifty-eight such operations, including two total (whole lung) extirpations. Six patients died as the result of the operation and fifty-one were cured without a fistula. Radical removal is not feasible in bronchiectasis of inflammatory origin. Here improvement may be obtained by collapse therapy and drainage of the pus cavities. The discharge is diminished, toxemia is lessened and damage to the kidney is prevented. The outlook for a cure, however, is not as good as after a radical operation. The rational treatment of congenital bronchiectasis consists of extirpation of the involved lobe. It is the method of choice and should be performed early, before the secondary alterations have time to develop.

Tumors of Parotid Gland.—Hintze reports 116 cases of parotid tumor observed at the surgical clinic of the University of Berlin between 1912 and 1933. Classification of parotid tumors on a histologic basis presented certain difficulties, since pathologists are not always agreed as to whether carcinoma or sarcoma is present and at times are unable to state definitely whether the tumor is benign or malignant. The surgeon must keep in mind the ever present possibility of malignant degeneration of a previously benign tumor. The author believes it advisable to consider malignant the so-called mixed tumors. The cylindromas, which may be either benign or malignant, are considered as a separate group. Of the fifty histologically proved malignant conditions of the parotid, there were fourteen carcinomas, sixteen sarcomas, three not clearly differentiated between carcinoma and sarcoma, twelve mixed tumors, four cylindromas and one lymphoma. Of twenty histologically proved benign tumors, fifteen belonged to the mixed group and three to cylindromas, while two were simple benign tumors.

The author emphasizes the fact that not an inconsiderable proportion of the mixed tumors are malignant. About one third of the histologically proved malignant cases had a long history suggesting malignant transformation of an originally benign tumor. The author sees in irradiation a powerful adjuvant to surgical therapy. He reports 45 per cent of five year survivals in the malignant cases, of which 21 per cent were symptom free at the end of this term. He sums up the therapeutic indications as follows: Every malignant or suspected tumor is given a single powerful roentgen irradiation. Should the tumor be roentgen sensitive so that within six weeks after the initial exposure it is reduced to one half its original size, the irradiation is repeated until no further reduction takes place. The use of radium is then resorted to. The tumors that do not respond to the initial irradiation are at once subjected to a radical extirpation, which is however followed by repeated irradiations to prevent recurrence. A recent recurrence is best treated by irradiation. The roentgen-insensitive recurrence must be treated operatively. The inoperable tumors are treated by intensive roentgen irradiation, after which it may be possible to do a partial resection of the growth and to implant radium. The likely paralysis of the facial nerve does not constitute a contraindication to therapy, since its involvement by the malignant tumor sooner or later is a foregone conclusion. The radical therapy in such cases is further indicated by the unbearable pain. Distant metastases can be retarded only by irradiation. A recent benign parotid tumor is best treated by irradiation. A progressive, even though slow enlargement, demands operative intervention even at the risk of facial palsy. Because of frequent recurrence and tendency to malignant degeneration, every case of a benign parotid tumor is to be subjected, after the surgical removal, to prophylactic irradiation.

*Effect of Iodine, Sympathetic, Vagus, Parathyroids and Suprarenals on Compensatory Hypertrophy of the Thyroid. N. Hoshiko.—p. 161.

Influence of Avitaminosis on Infection.—Takahashi noted a pronounced lowering of resistance to bacterial infection in his animal experiments in the presence of vitamin B and C deficiency. Multiple abscesses in the epiphyses of bones regularly occurred in vitamin C deficiency. Bony metastases of this type were observed exceptionally only in the control animals. The circulation in the medulla of metaphyses was found considerably altered in the absence of vitamin C. These circulatory disturbances together with the anatomic alterations in the medulla of the metaphyses exercised the determining influence on the localization and multiplication of the bacteria in this segment of the bone. The author concludes that vitamin C deficiency may be a factor in the genesis of acute osteomyelitis.

Biologic Action of Different Types of Goiters.—Kimura found that injection of thyroid extract in guinea-pigs definitely raises their basal metabolic rate while slightly raising their blood sugar. At the same time the respiratory quotient is somewhat lowered. The blood sugar rises shortly after the injection and returns to normal in five hours. The basal metabolic rate begins to rise only after five hours and remains so for a number of days. The respiratory quotient was regularly found to be at its lowest when the rise in the basal metabolic rate had lasted longest. Glandular substance characterized by thyrotoxic symptoms, high basal metabolic rate and the histologic picture of a hyperfunctioning gland was found to be not always the most active in the biologic sense. The author found that administration of iodine lowered the basal metabolic rate and improved the clinical symptoms, while the histologic picture was more that of a functionally resting gland. Extracts from such a gland proved to be far more biologically active. Apparently the active substance was abundantly secreted in these glands. Cystadenomas showed

without exception a low basal metabolic rate and a pronounced diminution of colloids. Their biologic action was almost absent.

Effect of Iodine on Compensatory Hypertrophy of Thyroid.—Hoshiko found that removal of one lobe of the thyroid in a guinea-pig was followed by a compensatory hypertrophy of the remaining lobe, as evidenced by an increase in weight and in the colloid content. When in addition to the hemithyroidectomy iodine in the form of 1 per cent compound solution of iodine was fed by mouth, it was found that the increase in weight of the remaining lobe was further increased but that the increase in colloid content continued only for eight days and that after eleven days no difference could be noted between iodized and noniodized glands. The effect of sympathectomy was to inhibit or, at least, to retard the increase in weight and in colloid content. Exhibition of iodine, however, again caused the increase in weight and in colloid. The author found that section of the vagus inhibited the compensatory hypertrophy but that under the influence of iodine the increase in weight and colloid again took place. The sectioning of the vagus and the sympathetic with simultaneous administration of iodine resulted in increase in weight and colloid, which corresponded to the average increase in experiments in which either the sympathetic or the vagus was sectioned. Storing of colloid was present in each instance. The effect of the removal of the parathyroids and of the suprarenals was to prevent the compensatory hypertrophy to a considerable degree. This inhibition could be counteracted by administration of iodine so that the increase in weight corresponded to that seen in the control animals, while the increase in colloid was even more pronounced than in the controls. On the basis of these experiments the author concludes that the thyroid is influenced by the autonomic nervous system and humorally by the interval secretions of the parathyroids and the suprarenals. These influences may always be counteracted by the administration of iodine. The effect of iodine consists in provoking a compensatory hypertrophy and in increasing the colloid content of the follicles. The storing of colloid under the influence of iodine is more pronounced if the influence of the sympathetic, the vagus, the parathyroids and the suprarenals is eliminated.

Tabetiform Manifestations Following Diphtheria.—Werner describes the clinical history of a woman, aged 28, whose main symptom was lack of the pupillary and the patellar reflexes. Congenital and acquired syphilis and all other disturbances that may cause tabetiform disorders could be ruled out in this patient. The anamnesis revealed that the pseudotabetiform syndrome appeared first at the age of 12, immediately following a severe diphtheria that was accompanied by prolonged visual disturbances and by impaired walking. The author designates the condition as postdiphtheric pseudotabes. He thinks that many of the obscure, pseudotabetiform disorders and many cases of tabes with negative serologic reactions may be of diphtheric etiology.

Suboccipital Puncture During Consultation?—Memmesheimer thinks that a physician who has mastered the technic well and who is familiar with the dangers is permitted to perform a suboccipital puncture in the consultation office. He discusses some of the details of the technic and shows how to avoid certain complications. He points out that the syphilologist often discovers cases in which an examination of the spinal fluid has been neglected because the patients feared a lumbar puncture and did not report at the clinic for a suboccipital puncture. As a result, an incipient disease of the central nervous system is overlooked and serious sequels result, whereas an examination of the cerebrospinal fluid at the right time would have permitted a prophylactic treatment. The author emphasizes that such cases may be avoided if the suboccipital puncture is done during the consultation hour.

Essential Hypertension of Pregnancy.—Seitz proves the existence of a hypertension, which is the result of the changes caused by pregnancy, in which all other symptoms are absent, and which disappears again during the puerperium (essential hypertension of pregnancy). This hypertension is an exacerbation of the increase in blood pressure that frequently develops at the end of pregnancy and is always present during delivery. It is a manifestation of the adaptation on the part of the organism that only by increased tension of its vascular walls is capable of accomplishing the changed and increased work required of the vascular apparatus during pregnancy. The blood pressure increase is to be considered as abnormal if it exceeds a certain height. Whether the hypertension of pregnancy ever becomes so severe that it threatens the life of the mother and makes an interruption of the pregnancy necessary cannot be determined as yet. The essential hypertension of pregnancy is the result of hormone influences, among which the reduction of choline and the increase of the hormone of the posterior lobe of the hypophysis in the blood play an important part. Women with symptoms of exophthalmic goiter or with plethora seem to be especially predisposed to essential hypertension of pregnancy. If it exists for longer periods and becomes rather high, it may influence other organs. It may cause nutritional disturbances in the parenchymatous organs (kidneys, liver, brain and others), and this in turn may lead to anatomic changes in the affected organs. However, in addition to the general increase in blood pressure, localized vascular spasms and the influence of toxic products on the cells play a part in the development of the organic changes. Thus the increased blood pressure that exists in toxemias is a symptom rather than the essential cause of the toxemias (symptomatic hypertension of the toxemias of pregnancy). An already existing essential hypertension often becomes exacerbated by a pregnancy. If the hypertension is severe, 250 mm. or more, and symptoms of decompensation appear, an interruption of pregnancy must be taken into consideration.

Intracutaneous Administration of Living Vaccine in Gonorrhea.—Sommer asserts that while the usual subcutaneous, intramuscular and intravenous administration of vaccines of killed gonococci is accompanied by severe general reactions, the intracutaneous administration of living vaccines causes none or extremely mild general reactions. The author employed the living vaccine in thirty-six women with gonorrhea. He reaches the conclusion that the intracutaneous injection of living vaccines presents a considerable progress in the treatment of the chronic gonorrheal processes of inflammation of the female sex organ. The method proved to be entirely harmless, and ambulatory treatment was possible. When employed in the correct manner, the treatment effected a cure even in those cases which relapsed again and again for months and even for years and which proved refractory to all other methods of treatment.

Anemias Caused by Iron Deficiency.—Schur attempts to bring the hypochromic anemias into one group. He shows that the large group of chloranemias may be brought under one heading in that they are varying manifestations of a clinical

entity. The different forms show gradual transitions and the essential factor is always a disturbance in the iron metabolism. The regulation of the formation of the blood is closely connected with the iron metabolism. The latter in turn is dependent on an undisturbed collaboration of numerous organic functions that make possible intake and resorption of iron, depot formation, mobilization of the depots and utilization for the formation of blood. The concurrence of several pathologic factors is as a rule necessary to effect a considerable disturbance. Anemias resulting from such disturbances should be considered from the point of view of the disturbed iron metabolism. Such anemias may be caused by deficient intake of iron, chronic loss of blood, disturbances in the resorption (achylia, achlorhydria, hypochlorhydria, gastric resection, chronic enteritis), disturbances in the endocrine and the sympathetic apparatus and systemic diseases with direct impairment of the blood forming organs.

Counting of Labor Pains and Prognosis of Delivery.—Siegert says that the larger the os uteri is at the time of the rupture of the bag of waters, the less is the number of labor pains required to complete the delivery. This corresponds to the rule that the total number of labor pains in a delivery is the greater, the smaller the os uteri is at the time of the rupture of the bag of waters. The author discusses the hour frequency, that is, the number of contractions in an hour. His observations convinced him that there is a rather constant ratio between the time required for the different periods of birth and the number of their uterine contractions. He assumes a law that governs the dynamics of delivery and formulates it as follows: (1) The longer the duration of the birth, the greater the number of uterine contractions; (2) there is a definite ratio between the work accomplished in the various periods of birth. In answer to the problem whether the absolute number of labor pains is a valuable factor in determining the prognosis and thus the management of a delivery, the author states that on the basis of the aforementioned deductions this is not the case, for the counting is of value only in connection with the duration of the process of birth. He emphasizes that, if after the rupture of the bag of waters the hour frequency of the uterine contractions decreases, this is an indication that the contraction capacity of the uterus slackens, and a spontaneous delivery becomes more doubtful as the number of pains each hour becomes smaller. He thinks that, if the obstetrician considers only the absolute number of uterine contractions, operative interventions will be resorted to more often than necessary. The number of uterine contractions per hour determines the course of birth in primiparas as well as in multiparas.

Hormone of Anterior Lobe of Hypophysis and Female Genitalia.—Stöckl describes observations on the internal genitalia of three women who were given intramuscular injections of a gonadotropic preparation of the anterior lobe of the hypophysis. The studies were made in women who had to undergo a surgical intervention on the genitalia, after preliminary tests had been made on animals. In the course of the days preceding the operation, the women were given several injections of the extract. The total dose varied between

200 and 400 mouse units. It was found that these injections induced a strong hyperemia of the pelvic organs, the appearance of blood-filled follicles in the ovaries, and, in a patient past the menopausal age, the formation of an unusually large corpus luteum. Changes were noted also in the uterine mucous membrane. The general condition of the patients remained unchanged, and disturbances were not noted during or after the injections. The author thinks that, in spite of the small material, his observations justify the conclusion that the administration of gonadotropic preparations produces in the internal genitalia of sexually mature women changes that are identical with those observed in animals following the administration of these substances.

Clinical Determination of Phosphorus in Blood.—Burkens found that in determining the inorganic phosphate of the blood made noncoagulable by means of oxalate, citrate or hirudin it is necessary to proceed immediately after withdrawing the blood to avoid a possible increase in the phosphate content. In some cases the orthophosphate content may diminish. The cause of this lies in the fact that the phosphoric esters disintegrate to and are built up from inorganic phosphorus. In the albumin-free trichloroacetic acid filtrate of blood and plasma, the inorganic phosphorus content is just as inconstant. Blood, serum, plasma or an albumin-free filtrate cannot be sent for an analysis. If the blood is made noncoagulable by the addition of 10 mg. of sodium fluoride (in powder form) to every 5 cc. of blood or by mixing with it 0.1 part of a 2 per cent solution of sodium fluoride, the blood or the plasma may be kept for a long time at room temperature or at 38 C. without showing any change in the concentration of inorganic phosphorus. The author concludes that phosphorus determinations are of clinical importance only when found in the blood of fasting persons because, after consumption of carbohydrates, there is a prolonged decrease in the phosphate content of the blood.

*Idiopathic Steatorrhea, with Especial Regard to Diagnosis and Occurrence of Symptoms of Endocrinopathy and Avitaminosis: Two Cases. T. E. H. Thaysen.—p. 1033.

*Investigations on Capillary Resistance: II. Reduced Resistance in Patients on Gastro-Intestinal Diet, Especially Ulcer Diet, and Its Affectibility by Vitamin C (from Berries of Dog Rose). P. Schultzer.—p. 1052.

Idiopathic Steatorrhea.—In the first and fatal case described by Thaysen, the symptoms of the disorder set in nine years earlier; in the second, the disturbance dated back to childhood. The first patient was a man, aged 32, the second a woman, aged 24. Both patients had been treated at home and hospitalized at various times. Abdominal tuberculosis had been suspected. The cases were treated under the diagnosis of Addison's disease, pluriglandular insufficiency and anemia. The author says that while there was marked pigmentation of the skin, neither of the patients had typical Addison's disease. Symptoms of endocrinopathy and avitaminosis appeared together. In the first case there were hemeralopia, pronounced tetany and pigmentation; in the second, dwarfism of hypophyseal type, glossitis, pigmentation, hemorrhages in the skin, osteoporosis and latent tetany. The anemia in idiopathic steatorrhea may be so marked as to dominate the entire picture, and the two attacks of grave anemia, which occurred in both cases, diverted attention from the steatorrhea. The diagnosis of idiopathic steatorrhea is not confirmed on the demonstration of an excess of fat in the stools. The presence of this abnormality without

jaundice or signs of occlusion of the choledochus calls for examination of the blood sugar curve after the administration of dextrose. If the blood sugar curve is low the diagnosis of idiopathic steatorrhea must be made, since neither pancreatic steatorrhea nor steatorrhea in intestinal amyloidosis nor intestinal tuberculosis is accompanied by low blood sugar.

Capillary Resistance.—After treating eighteen patients suffering from ulcer and having normal capillary resistance with a diet relatively deficient in vitamin C for an average of sixteen days, Schultzer found lowered capillary resistance in nine. A series of examinations in seventeen other patients also treated with a gastro-intestinal diet deficient in vitamin C confirmed this result. That the resistance was not reduced in all the cases is explained by the fact that different persons require different lengths of time to develop lowered resistance. The addition of vitamin C (in tablets of pulverized berries of dog rose) in seven cases restored normal capillary resistance in five; a cause other than avitaminosis was confirmed for the lowered resistance in one of the two cases.

*Elimination of Organic Acids in Urine During Childhood and Relation of Acids to Basal Metabolism in Adults. S. Siwe.—p. 157.

Murder or Suicide Due to Blows from Ax. F. Harbitz.—p. 266.

Organic Acids in Urine During Childhood.—Siwe states that the elimination of organic acids, both in the total amount and in the ether-free fraction, often varies considerably from case to case and in the same person from day to day. In premature and weak infants the values of the eliminated organic acids are higher than in normally developed children of the same age. The quantity of organic acids in the urine depends mainly on the intermediary metabolism. In grave acute nutritional disturbances in infancy the organic acid values are somewhat increased; in chronic nutritional disturbances the values equal those seen in weak and premature infants of younger age. In rickets the values are greatly increased, the total value rising considerably more than the ether-free fraction. In spasmodophilia, both increased and approximately normal values are found. In diabetes, establishment of the organic acids in the urine presents a simpler and more sensitive method for determination of the acidotic condition of the body than is afforded by the usual quantitative methods. As children grow older the elimination of organic acids per kilogram and day seems to diminish, and the daily variations become less. Cases of abnormally low organic acid elimination appear in childhood. There is a relatively constant ration of 3:2 between the organic acids eliminated during the day and during the night. Comparison between the basal metabolism and the organic acid elimination in adults shows no positive or negative correlation between the values. Instances of abnormally low organic acid values also occur in adults. The diagnosis in these cases points to disturbances in metabolism, sometimes of endocrine nature. The results of the author's examinations in eighty children are tabulated.

Investigations in Children from Tuberculous Environment. O. Lassen.—p. 1129.

*Investigation of Liver Function in Patients with Acute Febrile Disorders. K. Brøchner-Mortensen.—p. 1136.

Report of Fifteenth Continuation Course in Tuberculosis in Prince Regent Luitpold Children's Sanatorium in Scheidegg, Bavaria. 1934. H. Harpelt.—p. 1141.

Liver Function and Acute Febrile Disorders.—Brøchner-Mortensen found urobilinuria and urobilinogenuria in forty-nine of fifty cases of acute febrile disturbances, increased lipase count in twenty-two, and increased retention after the bilirubin loading test in thirteen. The bilirubin content of the blood was normal in scarlet fever. A marked reduction in the liver function set in rapidly in sepsis. There was also decreased function in one case of encephalitis, one of tuberculous meningitis, two of influenza and two of mononucleosis; in two cases of acute leukemia and two of mononucleosis the function was normal. Daily tests in twenty-nine cases showed that the increased urobilin elimination generally continued somewhat longer than the fever.

LUNG ABSCESS

CHAIRMAN'S ADDRESS

HAROLD BRUNN, M.D.
SAN FRANCISCO

In searching about for a subject that might be of interest, several things conspired to influence me in the choice of lung abscess. Any disease that has a mortality as high as this is a proper subject for consideration before this section. Of equal importance but less emphasized is the long period of disability and hospitalization, thus bringing about serious social and economic problems. Because this disease is not a very common one, because it is usually treated in the first instance by the family physician who has had no considerable experience with it, and because it is difficult from the literature to evaluate any particular form of treatment, I feel that a discussion of this disease may be of value.

It might at this point be interesting to relate that several years ago in the San Francisco Bay region a little group was formed, composed mostly of thoracic surgeons with a sprinkling of especially selected medical men. We formed ourselves into a dinner club. After a number of interesting meetings, the group finally split up on the subject of lung abscess. But we came to some interesting conclusions, which were that we knew but little about this disease in its clinical aspects, that the criteria which we had used were not built on fact, that to prognosticate the course of any individual case was fraught with difficulty, and that we could obtain arguments through the literature for any kind of procedure that we might wish to use.

With this previous experience it is therefore with some temerity that I appear before you, and I presume to do so only because a chairman's address permits of no discussion.

As a result of this experience, a rather intensive review was made of 128 cases from the records of the University of California Hospital, the Mount Zion Hospital, and the University of California service at the San Francisco Hospital. Through the courtesy of Dr. Leo Eloesser it was possible to add seventy-seven cases from the Stanford service at the San Francisco Hospital, making a total of 205 cases. When I started, I had certain preconceived ideas that I wished to prove. When I finished, I reached conclusions that were diametrically opposite. This study was carried on by a group composing the Thoracic Clinic of the Univer-

sity of California. They will report in the future, in detail, many of the points touched on in this paper which cannot be given full consideration here.

The cases were handled by a number of different men, some better trained than others in this special field; but the series does, perhaps, give a cross-section of the treatment and results in hospitals throughout the country. It is worthy of note that the seventy-seven cases from the Stanford service treated by Dr. Eloesser and his staff gave practically the same values as were obtained from the three hospitals mentioned.

Perhaps the subject might best be approached through a series of questions: Does the trouble in the handling of this disease lie in difficulty of diagnosis and early action on such diagnosis, as is the case with many acute surgical conditions? Are the diagnostic means at one's disposal always accurate, and does one lean at times too heavily on them? Is the complexity of the disease recognized and are insufficient data from a few cases too readily drawn on? Are medical practitioners carried away by any particular form of treatment and do they apply the various forms of treatment recommended, both medical and surgical, either at the wrong time or in the wrong case? Should cases be treated medically for a longer period or should surgical intervention come earlier in the course of the disease? Are there any criteria for the time of surgical intervention? Is there a possibility of improving surgical methods? If these questions have remained unanswered in the past, what are we, as surgeons, going to do about it?

I am limiting the scope of this paper to that type which had its beginning, at least, as an acute putrid abscess—foul smelling, containing elastic tissue, usually aspiratory in origin, and containing a multiplicity of bacteria, both anaerobic and aerobic; excluding bronchiectasis, abscesses on a carcinoma basis, and those produced by foreign bodies. For the purpose of this study 205 cases have been reviewed, hospitalized between the years of 1925 and 1934.

EXPECTANT TREATMENT

In the study of the literature, the dominant opinion expressed is that lung abscess should be treated medically or expectantly over a considerable period of time. There are no landmarks given as to when this treatment should cease; but it is often said that surgery should be done before the abscess becomes chronic, and this time is set arbitrarily at about six weeks to two months. The records seem to show, however, that surgery is seldom applied within this period.

Under the term of medical treatment I have included inhalations, postural drainage, bronchoscopy, artificial pneumothorax, phrenicectomy, arsphenamine and the

application of roentgen therapy. Space does not permit of prolonged discussion. Some of them, however, it would seem to me will bear consideration.

Surgical treatment includes only open drainage or lobectomy.

Postural drainage has been more generally advocated by internist and surgeon than any other one measure. I can find nothing in the literature that speaks of its disadvantages. Nevertheless I am cognizant of three cases in which death resulted from its application, and some warning may therefore be necessary in the use of this valuable procedure. Its advantages are not nearly so great in abscess as in bronchiectasis. It is valueless until an abscess has broken into a bronchus. To apply this remedy to a very sick patient—cyanotic, with high fever, rapid pulse and a low vital capacity—is courting disaster.

I myself know from personal experience how much easier it is to get material up from the bronchi in the sitting than in the lying posture; and I know how thwarted the diaphragm becomes in its expulsive efforts in the position of postural drainage. Experimental evidence verifies these clinical observations. Prinzmetal and Kountz¹ state that pulmonary ventilation is facilitated in the upright position. It has been shown that the vital capacity is generally higher, that the volume of the lung is greater, that the midcapacity is greater, that the accessory muscles of inspiration can be used to better advantage and that the diaphragm is lower than in the recumbent position. In their experiments on thirteen individuals, six of whom were without orthopnea and seven with, they found in all cases that the intrapleural pressure was less negative in the recumbent than in the upright position, and that the shift was more marked in the patients with orthopnea than in the control group. Occasionally the intrapleural pressure rose above the atmospheric pressure in the recumbent position. A less negative intrapleural pressure will limit pulmonary ventilation, and, according to the work of Starling, interferes with pulmonary circulation. The heart also shifts from a more longitudinal to a transverse position. Briscoe² states that, in the change from the upright to the supine position, the volume of the chest is reduced from 10 to 20 per cent and the reserve air by about 1,200 cc.

All these factors would work an even greater disadvantage in the position of postural drainage. It is easy to see, therefore, why this position might have brought about the death of the three patients mentioned. These factors also tend to produce compression and atelectasis of the lung, and, I feel, may so lower its resistance that infection may take place, with intrapulmonary spread.

Postural drainage has its place in the treatment of lung abscess; but it must be given with due consideration to the condition of the patient, the location of the abscess, and the direction of the bronchial tree leading from the infected area.

Bronchoscopy has its advocates. Here too is a procedure that cannot be carried out with sufficient frequency on a sick patient really to keep an abscess drained, as we say, surgically. Many have tried it only to give it up as a routine. It is not entirely void of the danger of setting up further inflammation.

Bronchoscopy is useful for the purpose of eliminating the possibility of a foreign body, for the diagnosis of a malignant condition or stenosis as a cause of the abscess and for the purpose of shrinking granulations to permit of better drainage through the bronchus; but as a routine for the cure of the disease it is, in my opinion, unsurgical.

For artificial pneumothorax, again, there are advocates who are enthusiastic, especially those who have used it as their routine in tuberculosis. If such therapy is employed, only small quantities of air should be used at each refill, and a negative pressure maintained. I would say, however, that most surgeons are fearful of adopting this mode of treatment. While some patients get well under its use, it is applicable to but few. It tends to break down adhesions, which is disadvantageous. A long period of time is required in its application thereby causing delay, especially when surgery is beneficial. It not infrequently causes rupture into the pleural cavity with formation of a putrid empyema, with a mortality of from 80 to 90 per cent. In my experience the risks of the procedure have not justified its use.

Temporary phrenic paralysis by crushing of this nerve is best applied for abscess of the lower lobe with adhesions to the diaphragm but has very limited application.

Arsphenamine as a cure has been unsatisfactory in my hands. While some improvement may occur in the general condition of the patient, I have not found it to be a specific agent, spirochetes still being present on careful examination.

The recent use of roentgen therapy to cause more rapid liquefaction of the abscess, early rupture into a bronchus, clearing up of surrounding pneumonitis and delimitation of the disease (as frequently happens when used in the treatment of carbuncles) is probably advantageous, but it has not been used in a sufficient number of cases to warrant a definite conclusion as to its value. I feel that, with careful studies as to proper dosage and time of application, roentgen treatment may prove to be a most valuable adjuvant.

X-RAYS IN DIAGNOSIS

The use of x-rays for diagnosis is most important. Physical examination is, at best, equivocal. The x-rays should be used frequently and are the best method of following the course of the disease. Roentgenograms should be taken in various directions, at least the antero-posterior and lateral, and sometimes with varying densities. Many medical men fail to use the x-rays sufficiently often, depending rather on their physical examination, in which they have a certain pride.

Useful as the x-rays are, they should not be relied on absolutely. Comparison of the roentgenogram with the postmortem examination frequently reveals this discrepancy. A cavity may be present but obscured by a surrounding pneumonitis. Liquefaction occurs early in this disease but may be undiagnosed by x-rays for a considerable period of time. When the pleura is thickened, much of the process is obscured and the x-rays lose some of their value. I have seen both small and large loculated empyemas, shown either by operation or post mortem, that had been missed completely by roentgen examination. In chronic cases even greater errors can be made as to multiple cavitations, and without the presence of earlier pictures taken months before it would be most difficult to diagnose even the location

1. Prinzmetal, Myron, and Kountz, W. B.: Intrapleural Pressure in Orthopnea, *Proc. Soc. Exper. Biol. & Med.* 31: 610-611 (Feb.) 1934.
2. Briscoe, Charlton: Mechanism of Inflation of the Lung, *Lancet* 2: 513 (Sept. 5) 1931.

of the abscess. So once again, without wishing to be a pessimist and recognizing, to the utmost, the value of the x-rays, I feel that one must at times base one's judgment on the clinical course rather than on the x-rays, if they do not verify one's conclusions.

The use of iodized oil seldom gives any information in lung abscess, as the cavity is almost never filled by the opaque medium, just as the cavity does not empty easily by postural drainage. It is of advantage when the abscess has broken into the pleura or is complicated by a bronchiectasis. Its disadvantages are great in that it remains within the lung for months at a time, and it is most difficult to read future roentgenograms. Many mistakes have been made in the reading of x-ray plates when it was not known that iodized oil had previously been employed.

BACTERIOLOGY

At this stage of the discussion a word should be said about the bacteriology of lung abscess. Efforts have constantly been made to find the etiologic agent of this disease. Until the present time this has proved a fruitless task. At first these studies were confined to aerobic organisms only; later they were supplemented by anaerobic studies, especially those of J. Cohn, Varney and D. T. Smith. Smith's studies have been by far the most complete. He concluded that four types of anaerobic organisms (spirochetes, vibrios, fusiforms and cocci), acting in symbiosis, are responsible for the inception of this disease. These bacteriologists have all demonstrated the similarity between the flora of abscesses and the flora of the buccal cavity, and that these flora are predominantly anaerobic. Olitsky and Gates have recently demonstrated the presence of filtrable forms in the nasopharynx. No studies on filtrable lung abscess material have as yet been reported.

In my own work, carried on in the laboratories of the Hooper Foundation under the direction of Drs. K. F. Meyer and M. S. Marshall, I confirmed the studies of Smith, but after careful bacteriologic study of bronchoscopic specimens I was unable to use the knowledge gained for either treatment or prognosis.

It would seem that this problem must be attacked now along the newer lines of bacteriologic research and immunologic studies. Under Dr. Charles Weiss and his co-workers, a new plan of procedure is being set up which, after a few years, I hope may give more information than has been available in the past. This work is based on the investigations of Avery, Heidelberger and Seegal, studying the purified nucleoproteins and specific carbohydrate fractions derived from various aerobic and anaerobic bacteria that have been frequently isolated from lung abscess. Along with this are cytologic studies and studies on the enzyme and antienzyme balance of the purulent pulmonary exudate.

MORTALITY

I believe it can be said that the lung has a better defensive mechanism for the resistance of infection than any other organ of the body, and that it has a wonderful recuperative ability. If this were not so, lung abscess would be a very common disease. The same organisms transferred to other parts of the body would give a mortality much higher than that of lung abscess. Every one will remember cases in which implantation has occurred in the chest wall after thoracentesis, causing spreading gangrene and necrosis and rapid death, with

practically 100 per cent mortality. We are, I think, forced to ask ourselves the question whether or not, surgically, we are treating this infection with the same ability and the same purposefulness, helping the forces which nature gave us, as we have learned to do in other parts of the body.

One cannot help but draw an analogy between the history of the treatment of acute appendicitis and acute gallbladder disease and that of lung abscess. So long as the expectant treatment held sway, no dent could be made in the high mortality of these diseases. The fact that under expectant treatment a certain number of cases improved caused physicians to hope that every case would fall within this group. As the result of similar procrastination in the treatment of lung abscess, the surgeon is faced constantly with the end-pathology of this disease: gangrene, hemorrhage, ruptures into the pleura, multiple abscesses, marked fibrosis and bronchiectatic dilatations. For this reason, I believe the course that has been followed in the past will get us nowhere in the battle against this very prolonged and exhausting disease.

May I also call attention to the fact that in this problem there is not only the question of mortality but also, bound up with it, the long hospitalization period, the economic and the social problem of months or years of disability, in many cases preventable. The picture is a tragic one from every standpoint, and difficult of solution; and we as surgeons should, I feel, concentrate on it.

THE HEALING OF LUNG ABSCESS

Certain basic principles underlie the healing of lung abscess, treated either medically or surgically. These are perfect drainage of the infecting material as in other surgical abscesses, aeration of its interior, and the ability of the cavity wall to collapse.

When a lung abscess heals by medical treatment, it must first rupture into a bronchus to produce drainage. Unfortunately, this drainage is often imperfect, resulting in the exacerbations that are so characteristic of the disease. These are ushered in by a rise of temperature and diminution of sputum, and as a result the disease may spread to new areas, producing either a pneumonitis or a secondary abscess. These bouts of fever are allowed to occur again and again without active intervention, which is quite contrary to the usual surgical procedure in abscesses of other parts of the body.

The second factor is the entrance of air into the cavity. As the causative agent is an anaerobe, the aeration of the cavity produces an unfavorable environment for its growth. This aeration is not always complete when rupture occurs through a bronchus.

In the third place, collapse of the walls is important and occurs best when the lung has retained its elasticity and before fibrosis has taken place.

ADVANTAGES OF SURGICAL TREATMENT

The advantages of surgery in meeting these requirements is evident. Perfect drainage of the abscess cavity can be obtained, leaving no undrained pockets from which extension can take place. Through-and-through aeration of the cavity and bronchi results. The importance of the through-and-through passage of air cannot be overestimated. This is exemplified in the surgical treatment of very chronic abscesses, with numerous and large bronchial fistulas. After months of drainage, if

the fistulas are closed by any method, there is recurrence of an abscess, even though the area is aerated on the bronchial side. Thirdly, by a liberal removal of the roof of the cavity, its early collapse is facilitated.

The choice of time and procedure in the surgical treatment of lung abscess will always require rare judgment. The condition of the patient is of more importance than the method of operating. At times only a minimal amount of surgery can be applied. Even a hypodermic of morphine may so lower the vital capacity that the patient becomes inoperable.

Chart 1.—Results of medical treatment.

There are certain important requisites that may be mentioned. These are (1) careful localization, (2) the performance of the operation in two or even more stages instead of one, (3) the use of the cautery or diathermy knife in exposing the abscess, and (4) the use of compression by a gauze pack or paraffin.

The first point of importance in technic is the careful localization of the abscess. Many studies on localization have recently been made: Neuhoff on a clinical basis, Leveton³ by anatomic studies of the lobes of the lung and the arrangement of the bronchi, and Johnson⁴ by roentgenologic studies in which localization is accomplished by measuring stereoscopic distance, with three markings on the chest. By any or all of these methods very accurate localization of the abscess can be made, which will give a direct approach to it at its nearest point to the surface and probably through the area of adhesion.

I have come to believe that the operation, whether it is to be done early or late, should always be done in two stages. Even late cases at times show surprisingly few adhesions; and in this type of case the element of compression before the abscess is opened plays a considerable part in its cure. In the early cases, in which only fine adhesions are present between the parietal and visceral pleura, the abscess may be entered through the line of adhesions; but if the patient coughs at the time of operation or at the time of a dressing, these adhesions may separate and the pleural cavity become infected.

In chronic cases the exposure of a considerable area over the lung abscess, with or without removal of the ribs, and the application of a pack of gauze or paraffin for from five to seven days, the wound being sewn up tightly as recommended by Dolly and later by Overholt, may have distinct advantage. I have on many occasions produced compression by such a pack, either as a planned procedure or because the patient was too ill to proceed further with the operation, and have been surprised at the improvement that has always taken place in the amount of sputum, diminution of cough and the well being of the patient. The second stage

is therefore done with the patient in very much better condition.

Another point of importance in technic is the use of the diathermy knife or cautery. Thorough cauterization of the top of the abscess should be made by slow coagulation. This avoids the danger of air embolism and the dislodgment of emboli. The plunging of a forceps or the finger into the cavity, with injury and trauma to the surrounding lung, is dangerous. In the report of cases to be given, I had one death from air embolism, and another presented convulsive seizures with recovery. Both of these were chronic cases and occurred immediately on the thrusting of an aspirating needle into the lung at the second stage, in an attempt to locate the abscess.

These are only a few points in technic that may help to lower the surgical mortality; but they can, at best, play an indifferent part. It would seem to me that the main problem of lung abscess at the present time is to change the attitude of the profession toward its treatment, just as the surgeon has changed the attitude of the internist toward the treatment of appendicitis and gallbladder disease.

RESULTS

The accompanying charts and tables give the results of the study of 205 cases. They graphically depict the weakness of present-day methods in the treatment of lung abscess.

Chart 1 shows the results of medical treatment. In 205 cases, 133 were treated medically. Sixty-three cases, or 31 per cent, were improved. Lord, in his recent statistics of 210 cases from the Massachusetts General Hospital, showed about the same results: one in three cases improved, or about 33⅓ per cent, under medical treatment.

Seventy patients died, a mortality of 35 per cent. Seventy-two cases, or 34 per cent, were referred to surgery, on an average of 460 days from the time of the onset of the disease, and were on an average of 154 days in the hospital before operation. It will therefore be seen that the patients treated medically who died and also those which were referred to surgery had an average time of medical treatment that was very prolonged; and, as I will show later, surgery could not overcome the handicap presented.

Chart 2.—Results of surgical treatment.

The second part of the chart again shows the prolonged stay in the hospital before surgical intervention—an average of over five months.

Chart 2 shows the results of surgical treatment, giving the average number of days from the time of onset until operation was performed. Forty cases, or 56 per cent, were improved but did not come to operation until an average of 415 days from the time of onset to operation. Thirty-two patients, or 44 per cent, died following operation. In this group, 516 days elapsed from the time of onset of the disease until operation was performed.

3. Leveton: Paper to be published.

4. Johnson, C. R.: Localization of Intrathoracic Structures, with Report Cases of Lung Abscess, *Am. J. Surg.* 8: 1237.

The second part of the chart shows the length of time these cases were treated medically in the hospital before surgery was advised.

Table 1 gives an analysis of the recurrences in 205 cases. After surgical treatment, twelve cases, or 6 per cent, recurred; after medical treatment forty-one cases,

TABLE 1.—Analysis of Recurrences in 205 Cases of Lung Abscess

	Onset	Per Cent
Recurred after surgical treatment	12	6
Recurred after medical treatment	41	20
Total recurrences.	53	26
Result of treatment in 53 recurrent cases		
Cured	8	15
Died	31	59
Outcome undetermined*	14	26
Total	53	100

* Lesion still present clinically and by x rays when last seen

or 20 per cent, recurred, a total recurrence of fifty-three cases, or 26 per cent.

It should be remembered at this point that no doubt some of the patients who were discharged as improved under medical treatment had recurrences. This is further shown in the second part of the chart. In

TABLE 2—Results of Surgical Treatment According to Type of Operation

	Per Cent	Pa tients	Improved		Died	
			Pa tients	Per Cent	Pa tients	Per Cent
Two stage thoracotomy	39	28	19	68	9*	72
One stage thoracotomy	44	32	15	46	17	64
Cautery pneumonectomy	85	6	3	50	3	50
Lobectomy	85	6	3	50	3	50
Total	100	72	40	56	32	44

* Two patients died before second stage was done

these recurrences eight patients, or 15 per cent, were cured and thirty-one patients, or 59 per cent, died. Patients who are discharged from the hospital and have recurrences are subject to a higher mortality.

Table 2 shows the surgical treatment and results according to the type of operation in one and two stage

TABLE 3—Surgical Treatment of Patients Operated on Within One Hundred Days from Onset*

Comparison of one and two stage thoracotomies					
20 Patients	No of Patients	Improved		Died	
		Patients	Per Cent	Patients	Per Cent
Two stage thoracotomy...	10	8	80	2	20
One stage thoracotomy .	10	4	40	6	60

* Arbitrarily chosen.

thoracotomy, performed on seventy-two patients previously mentioned.

Twenty-eight patients, or 39 per cent, had a two stage thoracotomy. Of these, nineteen patients, or 68 per cent, improved; nine patients, or 32 per cent, died.

Thirty-two patients, or 44 per cent, had a one stage thoracotomy. Of these, fifteen patients, or 46 per cent, improved and seventeen patients, or 64 per cent, died.

This very marked contrast shows the advantage of two stage thoracotomy. In six cases of cautery pneumonectomy included, three patients, or 50 per cent, improved and three patients, or 50 per cent, died. These and the cases of the lobectomy group were of long duration (about four and one-half years) complicated by marked bronchiectasis and fibrosis.

In table 3 I have arbitrarily taken patients of the operative group 100 days from the onset of the disease. Of twenty such patients, ten had a two stage thoracotomy and of these, eight patients, or 80 per cent, improved, two patients, or 20 per cent, dying. Of ten patients with one stage thoracotomy, four, or 40 per cent, improved and six, or 60 per cent, died. This shows the advantage of the two stage over the one stage thoracotomy.

Chart 3 shows the causes of death in medically and surgically treated cases, and the time of death from the onset of the disease.

The causes of death under medical and surgical treatment are very similar, and brain abscess and hemorrhage

MEDICAL TREATMENT, CAUSES OF MORTALITY

	Time from onset until death	
*77% or 54 cases Intra-thoracic spread	173 days	
9% or 6 cases Hemorrhage	268 days	
45% or 3 cases Brain Abscess	690 days	
25% or 2 cases Air Embolus	321 days	
45% or 3 cases Septicemia	105 days	
25% or 2 cases Myocardial failure	25 days	
Totals	100% or 70 cases	

*27% or 14 cases ruptured into the pleural cavity.

SURGICAL TREATMENT CAUSES OF MORTALITY

	Time from onset until death	
47% or 15 cases Intra-thoracic spread	91 days	
25% or 8 cases Hemorrhage	891 days	
19% or 6 cases Brain Abscess	1308 days	
9% or 3 cases Air Embolism	680 days	
Totals	100% or 32 cases	

*3 cases or 9% ruptured into the pleural cavity all before operation

Chart 3—Causes of mortality.

occur late in the disease. It would be only fair to believe therefore that, had operation not been undertaken, death would have occurred from similar causes under medical care.

CONCLUSIONS

In this paper I have been hypercritical and perhaps dogmatic concerning our present methods of treatment. Many will take exception to much that I have said. I am glad, however, to stir up argument and debate on this subject. Because patients get well under any and all forms of treatment, at times miraculously, it is not easy to evaluate the advantages and disadvantages of any form of treatment that may be suggested.

The tables and charts that I have presented, which I believe are not far different from other series that may be made on this basis, show definitely that both the medical man and the surgeon should take a more positive action in the treatment of lung abscess.

I hope that at some time a group report of cases throughout the country may be made under the auspices of some central body whereby both accurate statistics on the incidence, mortality and hospitalization period would be obtained and a better knowledge of the treatment of the disease disseminated throughout the profession.

COMPLICATIONS OF PEPTIC ULCER

THEIR PROGNOSTIC SIGNIFICANCE

SARA M. JORDAN, M.D.

AND

EVERETT D. KIEFER, M.D.

BOSTON

The more recent observations on peptic ulcer have produced many changes in opinion. Many dogmas formerly held in high esteem have been discarded, to be supplanted by beliefs that would once have been regarded with suspicion. This change in sentiment has concerned various phases of the ulcer problem—the nature and etiology of the lesion itself, the preferred status of medical or surgical treatment, and the outlook for permanent cure of the lesion.

These questions are all interrelated and their true answers depend at least in some measure on a still unsolved problem, the basic etiology of the disease. It has gradually become obvious that one must think not of cure of the disease but rather of "successful management." In fact, it may be stated that the life history of ulcer in an ulcer-bearing individual ends only with the life of the individual.

The successful medical management of the disease, the purpose of which is to produce a remission and prevent a recurrence, depends on various intrinsic and extrinsic factors. Such well known factors as limitation of nervous tension and fatigue and adherence to a careful regimen of living are at least relatively within the control of the patient and the physician. The intrinsic factors, on the other hand, comprise (1) the nature of peptic ulcer in general and (2) the nature

of the individual ulcer, particularly its location, size and complications. These are the uncontrollable factors with which the ulcer patient must reckon, and while they are not controllable factors they provide for the student of the ulcer problem many pertinent considerations. Especially interesting is the matter of outlook for successful management in ulcers with various complications.

Chart 1.—Uncomplicated duodenal ulcer.

This study was an effort to provide some data on the specific question Is a duodenal ulcer with one of the common complications less successfully managed than an uncomplicated duodenal ulcer?

The data were assembled from the case records and check-up reports of patients whose diagnosis was reasonably certain, and who were followed for periods varying from six months to ten years.

The complications considered in this study were pyloric obstruction, hemorrhage and intolerance to alkali therapy.

Read before the Section on Gastro-Enterology and Proctology at the Eighty-Fifth Annual Session of the American Medical Association, Cleveland, June 14, 1934.

OBSTRUCTION

The criterion used as evidence of obstruction was gastric retention of part of the barium meal for six hours. Gastric retention in these cases can safely be assumed to be associated with pathologic changes, since other extraneous and transitory causes of pylorospasm were ruled out by repeated examination.

In the consideration of pyloric obstruction associated with duodenal ulcer, the following points were studied:

1. In what percentage of cases does medical management relieve the obstruction?
2. How often does obstruction recur in these cases?

Chart 2.—Duodenal ulcer with obstruction.

3. Is the ulcer complicated with obstruction less amenable to successful management than the uncomplicated ulcer?

4. Does the degree of obstruction influence the prognosis?

The group studied comprised seventy-nine cases, fifty-six males and twenty-three females. In 77 per cent of the cases the age of the patient was above 40 years. In 68 per cent of the cases the duration of symptoms before help was sought

was over five years, suggesting that long standing inflammation and edema were partly responsible for the onset of obstruction. Vomiting, the commonest symptom indicating obstruction, was found as follows: spontaneous vomiting in sixty-five of the seventy-nine cases; self-induced vomiting in three cases; in eleven, no history of vomiting was obtained.

The four questions proposed were answered in this study by the following data:

Of the total group of seventy-nine cases, only 11 per cent required surgery for the immediate relief of obstruction. Relief was obtained in the other seventy cases (89 per cent) by hospital management for from one to three weeks, indicating that in the majority of cases obstruction is due to inflammatory changes, spasm and edema, and not to cicatrix or hyperplasia. The degree of obstruction was of no significance as far as relief by medical management was concerned, equal relief being obtained in patients with over 50 per cent retention as well as in those with 10 per cent or under.

In twenty-four, or 34 per cent, of the seventy patients relieved by medical management there were recurrences, but only nine of these had obstruction. Distress alone or with hemorrhage occurred in the other fifteen. Thus it appears that the obstructing lesion is not a distinctive type of ulcer but that obstruction may be a complication in one attack, and hemorrhage or distress without gastric retention may occur at another.

The question whether obstruction as a complication decreases the possibility of successful management is perhaps best answered by the following data:

The tendency to recurrence in a given group of patients may be more graphically shown by plotting the percentage remaining symptom free against the number

of years that has passed since the treatment was begun. Our experience with 148 cases of uncomplicated duodenal ulcer followed for five years or longer is represented by chart 1, which shows the rate at which relapses occurred. Although somewhat steeper in the first year the curve quickly assumes the character of a straight line, the direction of which is unchanged at the five year point. This indicates that the arbitrary choice of a five year period in the study of the end results of

Observations in Seventy-Nine Cases

	Number of Cases	Relief by Medical Management	Type of Recurrence		
			Distress Only	Obstruction	Hemorrhage
Group 1 (10% retention or less)	15	86%	1 case		
Group 2 (10 to 30% retention).....	19	89%	2 cases	4 cases	2 cases
Group 3 (30 to 50% retention).....	18	89%	2 cases	3 cases	1 case
Group 4 (over 50% retention).....	27	89%	3 cases	2 cases	4 cases
Total.....	79	70 cases	8 cases	9 cases	7 cases

treatment is unjustified, since the tendency to recurrence is just as great at the end of five years as it was during the previous years. In fact, a sufficient number of recurrences are known to have occurred in the sixth year to continue the curve in the same direction.

Of twenty-two cases complicated by pyloric obstruction followed for five years or more, there was recurrence in twelve cases: six in the first year, one in the second year, two in the third year, one in the fourth year, and two in the fifth year. Chart 2 shows a comparison of these figures with those of uncomplicated cases, from which comparison it may be concluded that obstruction as a complication makes the prognosis somewhat less favorable than in the uncomplicated case. The difference in the recurrences at the end of five years is 19 per cent.

Very mild obstruction, 10 per cent or less, apparently has no effect on the prognosis, but gastric retention of more than 10 per cent has an unfavorable influence; but it does not parallel the degree of obstruction.

HEMORRHAGE

In a group of forty-two patients giving a history of one gross hemorrhage, 17 per cent were found to have had a recurrence during the first year, and during the first five years 43 per cent experienced a recurrence, leaving 57 per cent with an uninterrupted remission. This indicates that hemorrhage is a sign of a somewhat more severe type of ulcer and has some, but not marked, prognostic significance.

The history of two or more gross hemorrhages is decidedly more serious. In a group of nineteen patients with this history, only 21 per cent remained free from a recurrence for five years. In another group of thir-

teen cases, followed for only two years, there were 54 per cent with recurrences. In nearly all cases the recurrence was in the form of another gross hemorrhage. Since the mortality of gross hemorrhage is 5 per cent, we frequently advise patients giving a history of two or more gross hemorrhages to have the ulcer removed.

Curves representing the groups presenting hemorrhage show a more rapid rate of recurrence. The group with two or more hemorrhages shows a particularly rapid rate during the first three years, but the change in direction here suggests that the first three years are the critical years for a patient of this type. The prognostic significance of multiple hemorrhages appears to be definitely bad.

ALKALOSIS

Alkalosis from alkali medication is a complication of therapy arising only when efforts are made to neutralize the stomach contents with sodium bicarbonate. Many patients may develop toxic symptoms at some time during their treatment, but in nearly all cases the condition is mild or transient and is easily relieved by adjusting the dosage of alkalis. A few patients, however, show a high degree of intolerance to sodium bicarbonate, and any dosage even approaching adequate control of gastric acidity produces severe symptoms of alkalosis. It has been shown that there is a definite association between intolerance to alkalis and impaired renal function, but clinical experience suggests that the etiology is much more complicated than this. There appears to be a marked correlation between the degree of intolerance to alkalis and the activity of the ulcer. Severe alkalosis may therefore indicate a particularly severe lesion and a marked disturbance in gastric secretion, as well as renal disease. That these patients do not do well under medical management is shown by our experience with twenty patients, among whom 70 per cent had a recurrence within two years.

The curve representing this high rate of recurrence shows a marked variation from the "standard."

CONCLUSIONS

Obstruction, hemorrhage and intolerance to alkalis are complications that influence prognosis in the medical management of duodenal ulcer.

Obstruction of all degrees in the group of seventy-nine cases studied was relieved in 89 per cent by medical management. It recurred later in 13 per cent.

Obstruction, hemorrhage and intolerance to alkalis were all unfavorable factors in the medical management of the disease. Single hemorrhage had the least effect on prognosis; obstruction was next in its unfavorable influence; multiple hemorrhage and intolerance to alkalis had the most harmful effect on the later course of the disease.

Chart 3.—Duodenal ulcer with history of hemorrhage.

ABSTRACT OF DISCUSSION

DR. BURRILL B. CROHN, New York: It is essential in discussing obstruction to realize that spasm is probably a much greater element than organic obstruction. This was taught by Sippy many years ago when he showed the remarkably good effects that could be obtained by lavage in cases of ulcer with retention. One is surprised to see complete disappearance of food stasis in patients who have as much as twenty-four or forty-eight hours residue, on using an Ewald tube to lavage the stomach. These are instances of spasm and they are in an entirely different category from obstruction. A patient should be taught to use an Ewald tube to empty his own stomach once a day. If he empties his stomach every night he may not be cured, but he is relieved of the symptoms and may go on for years. It represents a long history, a burnt-out ulcer. In cases of organic obstruction the ulcer in resected specimens is practically nothing but a small mass of scar tissue, and the pylorus is down to the size of a quill. Those patients must be operated on; no palliative treatment is good in the long run. My figure for the mortality of hemorrhage was less than 5 per cent. Actually in a series of 100 cases I found mortality of acute gross hemorrhage to be as low as 2 per cent; that is an important figure to keep in mind. There shouldn't be so much panic over gross hemorrhage. Such cases can be treated medically. It is better to accept defeat in 2 per cent than to be panicky about 98 per cent and take a radical position of advising operative treatment. If one does not roentgenograph an ulcer patient soon after a gross hemorrhage, one is liable to miss the ulcer. The hemorrhage seems to have an immediate effect in causing the healing of the ulcer. If one waits ten days or two or three weeks after the hemorrhage, it may no longer be possible to recognize the ulcer. Specimens of ulcers resected three weeks after gross hemorrhage showed complete healing of the ulcer and disappearance of the lesion. My experience is that if patients survive the first hemorrhage they are likely to survive repeated hemorrhages. The ultimate prognosis of the ulcer is not altered by the incidence of hemorrhage. The ultimate course of the case is about the same with or without hemorrhage. Eventually Dr. Jordan's and Dr. Kiefer's and my figures will come down to about 40 per cent of ultimate cures, and yet 40 per cent of ultimate cures under the medical treatment of ulcer is not a good percentage. The problem is one between the patient and his ulcer, not between the patient and his doctor or his surgeon. The patient has to learn to treat the ulcer with respect and not abuse it with alcohol or mental and physical strain.

DR. J. TATE MASON, Seattle: Since the first description of peptic ulcer was made, nearly a century ago, I am sure that no paper has been presented that has given such an intimate understanding of what may happen in complications such as hemorrhage, obstruction and intolerance to alkalosis as Dr. Jordan and Dr. Kiefer's paper has just given. I think that in these vicinities there might not be 11 per cent; however, as 11 per cent of the people had to come to operation almost immediately for relief, and a little further on 13 per cent, and probably in time a few more, it may be inferred that probably at least 25 per cent have had surgical intervention. I would pray that if patients with complications do not respond very rapidly to medical treatment, one should not hold them too long until one advises surgical relief. The operation must not only eradicate the diseased portion and the ulcer but also relieve the acidity. The surgeon will be able to do that either with the pyloroplasty or with the gastro-enterostomy, or he may eliminate acidity by a subtotal gastrectomy. And I present this problem not with reference to the technical side but to suggest that, if one decides that a patient must have a subtotal gastrectomy, one ask for a high subtotal gastrectomy to eliminate the acids, almost as high as for a near total gastrectomy in these very pronounced cases. Physicians at this meeting come from nearly all sections of the country, but I come from the far Northwest, and many of my patients live thousands of miles away. They have to go back to Alaska and stay for months at a time, and this has to be considered seriously in regard to medical treatment. The casual, ambulatory treatment has been satisfactory in 60 per cent of uncomplicated

cases of duodenal ulcer in the clinic with which I am affiliated. By treatment they were gotten to an uncomplicated stage, and from that time on a casual ambulatory treatment was as successful as any other. Serious hemorrhage after medical treatment occurred in 6 per cent of the patients. A mortality of 2 per cent attributed to hemorrhage occurred in a follow up of from two to ten years. I have observed that two thirds of the bleeding is apt to occur during the silent period; if it occurs in the period of erosion, it is likely to be much more severe.

DR. HENRY A. RAFSKY, New York: Pyloric obstruction, complicating peptic ulcer, must be divided into the inflammatory and cicatricial types. This differentiation should be made before attempting to treat pyloric obstruction, because the inflammatory type can be treated medically whereas the cicatricial type should be treated surgically. Clinically and roentgenologically it is almost impossible at times to make this distinction. The therapeutic test must be applied to do so, and various methods have been suggested for these patients. I want to show a method that can be easily applied, but before I do that I want to say a word about alkalosis in relation to pyloric obstruction. Patients with pyloric obstruction have a greater tendency to alkalosis; therefore, alkalis should be used with caution in these patients. I have found that by using very small amounts of alkalis in patients with pyloric obstruction, irrespective of how profound the stenosis was, the carbon dioxide combining power of the blood did not rise, and the blood chlorides did not fall beyond the normal limits. The tube has a prognostic as well as a therapeutic value; for, if the bucket and tube go through the pylorus in four or five days, the chances of making a recovery are good, but, if it does not go through, the patient is apt to have a recurrence of the symptoms within a very short time. It is sometimes difficult to get the bucket through the pylorus. What I did, following the suggestion made by Dr. Einhorn, was to take a small bead with a string and harness it to the duodenal bucket. The bead and string act like a team of horses and pull the bucket and tube through the pylorus, when the inflammatory process subsides somewhat.

DR. JULIUS FRIEDENWALD, Baltimore: I should like to refer again to a complication presented by a definite though small group of cases of pyloric obstruction of a rather aggravated type, which have yielded to medical management. All these cases were of long duration, presenting the typical signs of the disease as well as very definite roentgen changes, so that there can be no question that the condition must have been definitely due to actual tissue narrowing. Lucas, Vander Hoof and others have reported similar instances. It is possible that, owing to medical treatment, pyloric congestion and edema are relieved and the muscular tone of the stomach sufficiently improved to overcome the effect of the pyloric lesion. I have collected ten or twelve instances of this type among cases which have been permanently relieved over a period of from six to eight years, not only remaining free from all digestive symptoms but also revealing normal motor function as well as roentgen evidence. This group, though small, is perfectly definite, and I am convinced that in at least some instances of pyloric obstruction due to ulcer a favorable prognosis may be anticipated even without the aid of surgery.

DR. WALTER L. PALMER, Chicago: I should like to draw a rather fine line between the healing of an ulcer and permanent cure of the disease. Many of these lesions heal completely, and the patients may remain symptom free for variable periods of time, perhaps six months, six years or more, and then have a recurrence. This does not reflect at all on the efficacy of the initial treatment for the original lesion. It does show, however, that the therapy has not altered the fundamental conditions which led to the formation of the ulcer originally. These have persisted and have led to the development of a new lesion. The problem, therefore, is not that of the therapy of a given lesion but that of etiology, of preventing ulcer formation. I should like to call attention to one observation which Drs. Jordan and Kiefer have made; namely, that there was a 70 per cent recurrence in two years in the group intolerant to alkali. This high incidence of recurrence seems to me of great significance, for it constitutes further evidence of the importance

of gastric free acidity in ulcer. Mention has been made in the discussion of the beneficial effect of hemorrhage on an ulcer. I believe that this is due to the careful and prolonged treatment which the patient usually receives following a hemorrhage, rather than to a specific effect of the hemorrhage itself.

DR. RALPH C. BROWN, Chicago: The conclusions of the authors agree with my experience at the Presbyterian Hospital. There is a point I want to make with regard to alkalosis. It is not as simple a thing as one would like to believe. As the authors said, there are cases in which the basis of the alkalosis is absolutely not understandable. It may occur in the young individual with a perfect renal function, with normal arteries, with a good liver, and yet there will be just as striking an idiosyncrasy for alkalis as some persons exhibit for belladonna. Fortunately these cases are rare. The cases in which one runs into difficulty with alkalosis, and they are certainly not uncommon, are those in which one is forced to combat the destructive effect of a high grade, continued night secretion, and the only way that can be done is either by giving alkalis or keeping up a continuous aspiration of the stomach during the night hours with the Rehfuß tube. In these cases, especially in the obstructive cases, in which the chloride ion is being lost from the body by vomiting or by the aspiration of a large volume of gastric contents, with a drop in chlorides to 300 or 350 mg., one cannot safely give alkalis by day and also by night. One solution of the difficulty is to use the acid-combining power of milk as a neutralizing medium. There is sufficient albumin in milk to neutralize an equal volume of normal gastric juice. During the first week of management in these difficult cases of ulcer with a high grade continued secretion, I frequently give milk in 2 ounce feedings every half hour during the day. This permits the use of alkalis during the night hours, or, if one wishes to avoid entirely the use of alkalis for a brief period, the continued night secretion can be handled by half hour aspirations, as by an indwelling Rehfuß tube.

DR. SARA M. JORDAN, Boston: There are two words that will probably need further explanation. One is the word "obstruction," which we used in that paper to indicate any retention of barium in six hours. Dr. Crohn in his discussion said that retention by spasm was not obstruction. We considered it in this discussion as being the obstruction due to any cause and indicated by retention in six hours. The fact that 11 per cent of the patients had to be operated on during the first three weeks of treatment seems to us to indicate that probably in the highest majority of that 11 per cent the obstruction was due to cicatrization, whereas in the other 89 per cent who went on and were completely relieved of the obstruction it was due either to spasm or inflammation or to edema, and there was no way in which we could determine which did cause the retention. The other word which I think needs explanation is the word "recurrence." We have said that a certain percentage of the cases in the uncomplicated ulcer recur after so many years. By "recurrence" we mean any distress, not necessarily requiring surgery, but any distress which indicated that the ulcer was again active, frequently not as serious as the original distress, and frequently relieved by a very modified form of management; so it is not always a serious recurrence of which we are speaking. Dr. Crohn mentioned the fact that we were, or people were, getting panicky about hemorrhage, and I must confess that in multiple hemorrhage we have perhaps not gotten panicky but very serious minded, and we not infrequently feel, in a case of long-standing multiple hemorrhages, that the patient should not waste any more time on medical treatment but should have surgery and, where it is possible, we advise, as Dr. Mason said, a high resection. This may seem very radical. I was surprised that Dr. Crohn was so conservative about getting panicky on the question of introducing surgery, but we really do feel that in this particular group of cases surgery and high resection are indicated to produce an anacidity. With respect to the question of whether or not that repeated hemorrhage is due to the old original ulcer, a point which Dr. Palmer brought up, or to the fact that the patient has a tendency to develop an ulcer, that must, of course, be left undetermined in most cases; but frequently the condition found at operation will seem to indicate that it was the old, original ulcer which had partially healed and then become

eroded again, exposing, perhaps, the same blood vessel. Surgery seems to be the only treatment in those cases. The therapeutic test which Dr. Rafsky mentioned is interesting. We feel that our best therapeutic test is the period of medical management. If the obstruction is relieved in a few days or weeks, we consider that it is a very final therapeutic test or treatment.

CLINICAL OBSERVATIONS IN ONE HUNDRED CASES

JULIUS FRIEDENWALD, M.D.

AND

MAURICE FELDMAN, M.D.

BALTIMORE

During the last few years, increased interest has been manifested in the study of disturbances of the duodenum. While up to a comparatively short time ago ulceration of the duodenum was the only disease that was clearly defined and its significance understood, the clinical importance of duodenal dysfunction in general has gradually come to be more and more realized as a factor in disease. Of the disorders associated with this portion of the bowel, duodenitis, periduodenitis, pericholecystic adhesions, duodenal stasis (continuous and intermittent), obstruction and duodenal anomalies such as diverticula and the redundances may be mentioned.

In this communication we shall endeavor to present the clinical picture of a not uncommon form of duodenal disturbance known as the irritable or unstable duodenum.

Disturbances of motility of the duodenum have long been known. Wheelon¹ has especially called attention to these changes in obstruction in this portion of the bowel and has pointed out that duodenal motility consists of rhythmic segmentation and peristaltic waves, which bear a definite relation to that of the pyloric sphincter and antrum. The regurgitation of bile and fecal matter in cases of intestinal obstruction is the result, according to this observer, of active antiperistaltic contractions with a loss of rhythmic segmentation followed by tonic closure of the pyloric sphincter, produced possibly by a toxemia. He, moreover, points out that rapid distention of the duodenum causes inhibition of the rhythmic segmentation and peristalsis. It has likewise been long established that lesions in the duodenum such as ulcer or duodenitis are commonly associated with a vigorous gastric and duodenal peristalsis, which can readily be visualized roentgenographically.

The irritable or unstable duodenum, like the irritable or unstable colon described by Kantor² and Jordan,³ is a condition which has as yet not been clearly defined and concerning which there still exists considerable confusion. The term unstable is the more preferable, since at times a decreased rather than an increased irritability is noted. As has been pointed out by Jordan in regard to the unstable colon, here too the underlying

cause must be sought in an imbalance in the neuromuscular apparatus of the duodenum leading to a motor dysfunction and possibly also, to a certain degree, of a secretory dysfunction without evidence of organic disease.

ETIOLOGY

Duodenal motility may be disturbed, according to Sensenich,⁴ without evidence of organic disease, as the result of mechanical, chemical, allergic, nervous or reflex causes.

In regard to the mechanical causes, aside from the congenital factors, the conditions favoring duodenal instability are adhesions and compression of the duodenum. Adhesions ordinarily involve the first and second portions of the duodenum. Especially important in this connection are adhesive processes coming as the result of chronic cholecystitis, adhesions between the duodenum and the hepatic flexure, and those formed as the result of visceroptosis or following abdominal operative procedures. Pressure on the duodenum producing this condition may result from spinal deformities as well as from growth involving abdominal organs such as the pancreas and from pressure due to ptosis of the right kidney. The chemical causes are manifested in the form of changes in the gastric secretion as well as from regurgitation of bile and duodenal contents

incidence occurred between the twentieth and fiftieth years. Of the 100 patients, eighty were men and twenty women. It is evident, according to our observations, that this condition is far more frequent in males than in females. According to our experience, too, the unstable duodenum occurs far more frequently than a survey of the literature indicates.

SYMPTOMATOLOGY

The symptoms of the unstable duodenum are by no means characteristic. This condition may simulate duodenitis, duodenal ulcer, cholecystitis, appendicitis or other abdominal disorders. With the duodenitis or duodenal ulcer-like syndrome, symptoms of hyperchlorhydria are manifested with discomfort and postprandial pain. In other instances, when symptoms resemble those of cholecystitis, mild attacks of colic occur with tenderness in the gallbladder region. In others there is discomfort with localized pain in the lower right quadrant of the abdomen simulating appendicitis. There are some instances, however, in which the symptoms are quite atypical and in which the patient complains mainly of disturbed appetite, nausea, vomiting epigastric discomfort, and headaches. Abdominal pain is unusual, but when it does occur it is ordinarily mild in character.

The bowels are usually constipated, though intermittent diarrhea not infrequently replaces this condition. Duodenal stasis often of the intermittent type may be present and may account for certain symptoms. Owing to the patient's inability to consume a sufficient amount of food, loss of weight and strength is not unusual. Neurasthenic symptoms of a varied type are commonly present in the form of fatigue, depression, insomnia and irritability, adding further to the patient's discomfort. The symptoms associated with the unstable duodenum may occur in attacks with many periods of relief, extending over a considerable length of time during which the patient may enjoy comparatively good health.

In our series thirty-six cases presented symptoms suggesting duodenitis or duodenal ulcer, twenty-seven cholecystitis and twenty-two appendicitis. Loss of appetite occurred in fifty-six instances, nausea in twenty-three, vomiting in fifteen, epigastric discomfort in fifty-one, constipation in seventy-two, intermittent diarrhea in fourteen, duodenal stasis in twenty-four, and neurasthenic symptoms in sixty-eight.

REPORT OF CASE

The following history presents the most important features of a typical case of unstable duodenum simulating duodenal ulcer:

A. F., a man, aged 23, complained of indigestion for six months, consisting of discomfort and slight pain in the epigastrium, several hours following meals, which was relieved by the ingestion of food. The condition had recently become more constant and severe. The patient had lately complained of heartburn and acid eructations. He had always been greatly relieved of his symptoms by the ingestion of soda. Physical examination revealed no abnormalities. Tenderness in the epigastrium was absent. The gastric analysis showed a definite hyperchlorhydria. On roentgen examination the duodenal cap was found extremely irritable, filling well at times and not at others, but no deformity of the duodenum was observed. Pylorospasm was marked. As no lesion could be detected, the diagnosis of unstable duodenum was made, which was confirmed by subsequent examination.

into the stomach. This may be due to absorption of toxic material from duodenal contents retained as the result of disturbed motility in this portion of the bowel.

Gastro-intestinal symptoms due to food allergy are not uncommon, as Rowe,⁵ Gay⁶ and others have pointed out. Allergy has likewise been observed as a definite etiologic factor in certain instances of the unstable duodenum.

Derangement of the nervous system plays an important rôle in the production of this condition. It frequently arises in high strung nervous individuals and is especially noted during periods of overwork and fatigue, disappearing with rest and freedom from anxiety. In addition, general nervous symptoms such as headaches, palpitation, insomnia and depression are commonly present as evidence of its neurogenic origin.

It is interesting to note that the unstable duodenum is frequently of reflex origin, being the result of other disorders with which it is not uncommonly associated; of these, chronic cholecystitis with or without pericholecystic adhesions, cholelithiasis, gastric ulcer, chronic appendicitis and visceroptosis play an important rôle.

INCIDENCE

The material selected for this study of the unstable duodenum comprises a group of 100 cases. The highest

DIAGNOSIS

The patient is frequently of the high strung irritable neurasthenic type and often complains of various nervous symptoms such as headache, dizziness, insomnia and exhaustion. Loss of flesh is not uncommon. Spastic states may frequently be observed in other portions of the gastro-intestinal tract, such as cardiospasm, pylorospasm, gastrosplasm and spastic colitis, though in some instances, aside from the irritability of the duodenum, other involvements may be entirely absent.

The gastric analysis usually reveals an increased acidity. Occasionally, owing to the admixture of large quantities of bile, achylia may be present. Of the eighty-five cases in which gastric analyses were recorded, the gastric acidity was normal in twenty-nine; hyperchlorhydria was present in thirty-eight and hypochlorhydria and achylia in eighteen.

The diagnosis is usually extremely difficult from the symptoms alone. It should be suspected when in neurotic individuals symptoms of duodenal ulcer or cholecystitis or appendicitis occur which are not distinctly typical of these disorders. Such associations as the irritable or unstable colon, which was observed in fifty-one instances among our cases, is likewise suggestive of the presence of this condition. Of the associated conditions confirmed by roentgen examination in our cases, gastric ulcer was present in nine instances, chronic appendicitis in forty and cholecystitis in six. The liver was distinctly enlarged in four of our cases. It must, however, be borne in mind that many of these disorders may be definitely present as direct etiologic factors.

While the diagnosis is rarely possible from the history and physical examination, the roentgen evidence is far more conclusive. The roentgen signs of this condition are well defined and extremely characteristic, and a definite diagnosis can be made only by this procedure. These observations are based largely on fluoroscopic evidence by means of which changes in the form of the duodenal bulb as well as its motility can be carefully observed.

ROENTGEN STUDIES

The superior portion of the duodenum, also known as the cap or bulb, is the most frequent site in which the irritability manifests itself. The entire duodenum may present evidence of dysfunction, but in this study the irritability or unstable duodenal bulb alone will be considered. Normally the duodenal bulb fills and empties in a uniform rhythmic manner. It usually fills completely with ease and can readily be observed under the fluoroscopic screen. The contrast meal remains in the bulb only a few moments and then quickly spurts through into the second portion of the duodenum. During this interval the cap can be clearly visualized and a minute study made of its configuration and function. Any abnormality can thus be readily disclosed. In the milder types, slight variations from the normal are often difficult to interpret and may be overlooked. Frequently in the severe forms too, especially when there is extreme spasticity and irregularity, there is often doubt as to whether the condition is the result of an unstable bulb, a duodenitis or a duodenal ulcer.

The irritable bulb is characterized roentgenologically by the presence of (1) an increased motility with complete or incomplete emptying, (2) transient irregularities and fibrillation noted along the borders, (3) transient spastic manifestations, (4) tenderness and

sensitiveness over the duodenum, and (5) absence of a definite ulcer filling defect.

MOTILITY

The changes in motility in the irritable bulb may vary greatly in intensity from the mildest to the severest forms. However, the duodenal cap does not always empty itself completely, even though the motility is markedly accelerated. This is quite characteristic of the usual case. In some instances, too, the bulb may

empty so rapidly that it may become difficult to carry out the examination satisfactorily. At times the irritable cap may fill poorly, but ordinarily it becomes well filled. In none of the cases in our series was retention noted in the bulb but rather rapid emptying was most constantly observed. The bulb is often difficult to fill on account of the rather marked spasticity of the pylorus, which is by no means uncommon in this condition. Sluggish emptying of the cap was noted in only a small proportion of our cases.

Transient irregularities and fibrillation of the bulb occurred quite frequently and are of considerable importance in the diagnosis of the irritable cap. As an illustration, figure 1 presents this condition. The fibrillation is most clearly noted on the outer border and appears in the form of peristaltic waves moving in the direction of the second part of the duodenum. Under normal conditions fibrillations and peristaltic waves are rarely observed in the bulb, as this portion of the

Fig 2—Tracings made from fluoroscopic views, A, B, C and D showing the transient spasticities on the outer margin of the bulb. E, F and G illustrate similar changes occurring on the inner margin. Note the shifting of the spastic defects, with return of normal bulb outline.

duodenum ordinarily empties in mass spurts. Slight transient irregularities are also noted in this condition, often producing a transient fringed appearance of the border of the cap. No violent peristaltic waves, however, could be detected and no antiperistalsis was observed in our series.

Shifting spastic manifestations of the bulb occurred in 13 per cent of our cases (fig. 2). These spastic changes are revealed roentgenologically as transient deep indentations, which occur on one or both borders of the

cap. They appear most frequently, however, on one border alone and notably the outer. Their resemblance to ulcer filling defects are often marked, but on account of their transient nature the presence of an ulcer can usually be eliminated. It must be borne in mind, however, that these changes may in some instances indicate the presence of ulceration without the typical defect. Great care should therefore be exercised in drawing conclusions. Occasionally an hour glass deformity of the cap is detected. Attention must be directed to the fact that, when spasticity of a very intense degree occurs, the presence of an ulceration or duodenitis must at least be considered, for the roentgenologic distinction between irritable duodenal cap and duodenitis or ulcer is often only one of degree.

TENDERNESS AND SENSITIVENESS OVER THE DUODENAL BULB

In most instances in the presence of the irritable cap, a definite persistent point of sensitiveness is noted in the region over the duodenal area. This tenderness is, however, usually mild in type and not infrequently only a discomfort is elicited on palpation under the fluoroscopic screen.

ABSENCE OF AN ULCER FILLING DEFECT

We have not included in our study of the irritable duodenal bulb any cases in which the slightest evidence of a filling defect could be demonstrated or in which there was the least suggestion of ulceration; in fact, every roentgenologic and clinical precaution was undertaken to exclude such a possibility.

DESCRIPTION OF THE IRRITABLE DUODENAL BULB

The size and density of the duodenal bulb is usually normal; the shape in most instances is of the cone type and the margins are clearly and sharply defined. Elongation occurs but rarely. The reticular network and granular appearance of the duodenal bulb commonly observed in duodenitis is not noted in the unstable duodenum. The capacity of the duodenum may or may not be diminished. When completely filled, it has in all respects the roentgenologic appearance of a normal bulb.

Duodenal diverticula	3

In the study of the irritable duodenum, such disorders as duodenitis and duodenal ulcer must be excluded.

In duodenitis the presence of the irritable bulb is likewise a characteristic finding. According to Kirklin,⁷ four roentgen signs are observed in this condition: (1) irritability of the bulb, (2) unstable deformity producing a mucosal pattern of a coarse irregular reticular appearance attributed to spastic contractions of its muscularis, (3) absence of an ulcer crater and (4) absence

of gastric retention. In our study of the irritable duodenal bulb, not all these characteristics could be demonstrated. We did observe rapid emptying, transient fibrillating irregularity along the margins and transient spastic manifestations. These signs, however, were not constant throughout the examination, the bulb appearing perfectly normal in all instances during some period of the investigation. The characteristic mucosal pattern, such as lessened density and reticular granular

network of the bulb described by Kirklin, is not observed in this condition. However, it must be recognized that in some instances it may be extremely difficult to differentiate the two conditions.

The presence of duodenal ulceration must likewise be eliminated; this may become difficult, especially when the clinical manifestations point directly to this disorder. The transient roentgen signs are ordinarily sufficient to rule out this condition, but even here the slight bulbar manifestations might occasionally indicate extremely early changes as the precursor of an ulcer that has not as yet fully developed.

On the other hand, according to our experience with the unstable duodenum, there is frequently an associated generalized irritability and instability of the entire gastro-intestinal tract, indicating that this condition does not possess the localized characteristics observed in ulcer. In a few instances, however, duodenal ulceration not recognized at first was found in subsequent roentgen reexamination.

Other coexisting duodenal abnormalities, such as diverticula, redundancy, adhesions and stasis, were also noted. These appear in table 2. The second part of the duodenum also presented frequent changes in motility. Marked indications of irritability of the bulb are known to occur as the result of abnormal conditions present in the distal segment of the duodenum. A low grade stasis in the distal duodenum is likewise a common cause of this dysfunction.

Duodenal adhesions secondary to gallbladder infections producing signs of right upper quadrant adhesions occurred in 33 per cent of our cases. The presence of adhesions as a cause of this dysfunction is rather significant.

Gastric changes may likewise occur. The motility of the stomach as a rule is not unduly interfered with, retention occurring in but two cases of our series as the result of spasm. Gastric peristalsis is usually normal. Associated evidence of gastric disease was noted in nine instances in the form of ulceration (table 3). Spasticity of the pylorus is observed with striking frequency in this disorder; it was present in 42 per cent of our series. The roentgen ray revealed pathologic changes in the appendix in 40 per cent, and it is evident that the irritable duodenum in these instances is of reflex origin.

The spasticity of the pylorus and the irritability of the duodenal bulb and duodenum, together with the

7. Kirklin, B. R. A Roentgenologic Consideration of Duodenitis, Radiology 12: 377 (May) 1929; Duodenitis and Its Roentgenological Characteristics, Proc. Staff Meet., Mayo Clin. 8: 629 (Oct. 18) 1933.

frequent association of the irritable colon, suggests rather clearly that the entire gastro-intestinal tract may often be involved in this dysfunction.

The frequent simultaneous occurrence of adhesions or chronic appendicitis or colitis or gallbladder disorders as well as other intra-abdominal conditions that were noted in our series of cases is evidence, at least in many instances, of its reflex origin (table 4).

TREATMENT

The treatment of the unstable duodenum is usually satisfactory in most instances. This should be directed toward a restoration of this part of the bowel to its normal tone, which is best accomplished largely by means of diet, rest and improvement of the nervous system. As Jordan has pointed out, "the unstable colon can be due to a specific irritation of the neuromuscular apparatus of the colon without the involvement of the nervous system as a whole"; and so here too irritation from indigestible food, abuse of alcohol and excessive use of condiments as well as laxatives may play a rôle in the production of the irritable duodenum in some instances. On this account all irritating foods and remedies should be omitted. The food should consist ordinarily of an acid free bland diet of high caloric and high vitamin value. It should be taken in moderate amounts and given at regular and frequent intervals. At first, absolute rest in bed may be required for some weeks. As soon as improvement occurs, this may be reduced, though rest of half an hour following meals should be insisted on for a considerable length of time. In severe and intractable cases, duodenal lavage and feeding may be resorted to with great benefit. Special attention must be directed to the nervous system in those instances in which neurasthenic manifestations are prominent. Psychotherapy plays an important rôle in this regard.

When the condition is the result of such reflex causes as gastric ulcer, chronic appendicitis, cholecystitis or adhesions, treatment must necessarily be directed to the primary disorder. When hyperchlorhydria is present, frequent feedings and the moderate use of alkalis are indicated. Belladonna or atropine are efficient remedies in overcoming spasm. The use of cold or ice applications over the region of the duodenum will often afford temporary relief.

SUMMARY

The irritable or unstable duodenum occurs more commonly than a survey of the literature would indicate. The condition has as yet not been clearly defined, and considerable confusion still exists concerning its significance. The term "unstable" is suggested, since at times a decreased rather than an increased irritability is observed. The underlying cause is to be found in a disturbance of the neuromuscular mechanism of the duodenum, which may be the result of mechanical, chemical, allergic, nervous or reflex causes.

In a study of 100 cases of the unstable duodenum, the condition was found more frequently in males than in females and more commonly between the twentieth and fortieth years. The symptoms are by no means characteristic and the condition may simulate duodenal ulcer, cholecystitis, appendicitis or other abdominal disorders, though these may be actually present as direct etiologic factors. Nervous and neurasthenic manifestations are usually prominent. Gastric hyperchlorhydria is more commonly present.

Fig. 3.—A, a deep spastic defect is shown on the outer border of the bulb, at arrows. B, same case, illustrating the duodenal bulb completely filled, with slight irregularity on the outer margin. Note the absence of the spastic defect.

Evidences of instability and spastic states in other portions of the bowel are quite frequent. The diagnosis is definitely established by means of roentgen evidence. This consists in the detection of increased motility, transient irregularities and fibrillations, spastic manifestations and sensitiveness over the duodenum, together with an absence of an ulcer filling defect in this area.

The treatment must be directed to a restoration of the duodenum to its normal tone, which is best accomplished by means of diet, rest and improvement of the nervous system. In severe cases, duodenal lavage and alimentation may be resorted to with benefit. When this condition is the result of reflex causes, treatment must be directed to the primary disorder. Belladonna and atropine are effective remedies in relief of spasm.

1013 North Charles Street.

ABSTRACT OF DISCUSSION

DR. ELMER L. EGGLESTON, Battle Creek, Mich.: In this paper attention is called to the unstable or irritable duodenum, the symptomatology of which is quite varied and at times difficult to differentiate from biliary tract disease or acute duodenal ulcer. May I suggest that this so-called irritable duodenum, in a considerable proportion of cases, may be the result of a rapid emptying upper gastro-intestinal tract noticed when there is a disturbed vegetative nervous mechanism. The reference to the confusion of thought relative to both the irritable or spastic duodenum and the spastic colon is well taken, but opinion relative to the spastic or irritable colon is being clarified, and I believe there is a general agreement that the irritable colon is a result of an undue parasympathetic enervation of the distal colon. Fluoroscopic observation of a vagotonic individual reveals a rapidly emptying stomach, probably in less than half the normal time. The contents are highly acid with a high peptic activity, and if there is stasis in the duodenum, injury is likely to result, with symptoms not unlike those the authors mentioned. The authors call attention to a disturbed nervous mechanism but do not definitely designate the character of the derangement. My impression is that this unstable nervous state is responsible for the greater part of the functional disturbances of the gastro-intestinal tract and

possibly constitutes a decided predisposing cause of peptic ulcer as well. There are, no doubt, other factors, such as adhesions and disturbances in the biliary tract, that may be active as causes of the irritable or unstable duodenum. The picture may be due to a nervous instability, an undue parasympathetic enervation that occurs with undue emotional stress, overtenseness of the individual who is attempting to attain success by application over too long periods of time with too little sleep. The conception of gastro-intestinal disorders must not be based on dietetic disorders or focal infections alone. It must be recognized that disordered nervous states may be the principal causative factor.

DR. JOHN G. MATEER, Detroit: Drs. Friedenwald and Feldman should be congratulated for contributing to our knowledge of the duodenum. Gastro-enterologists and roentgenologists are agreed that too little attention has been directed toward duodenal abnormalities. Those who have had experience in gastro-intestinal fluoroscopy will agree with the authors' roentgen criteria of the unstable or irritable duodenum. Emphasis should be placed on the transient character of the localized irregularities of the duodenal cap, the tenderness noted so frequently on palpation of the bulb, and the generalized spasm and rapid emptying, which lead to temporary difficulty in satisfactory visualization of the bulb. These spastic phenomena of the unstable duodenum, with the transient irregularity of the cap, can be easily differentiated, as a rule, from the persistent spasm defect of duodenal ulcer. It is common knowledge that the bulbar deformity of the unstable duodenum disappears if the patient is given atropine or belladonna up to the physiologic limit. Furthermore, this type of deformity also disappears frequently with gentle manipulation of the cap or if one waits and observes the patient fluoroscopically a second time; e. g., fifteen or twenty minutes after receiving the barium meal. The authors' observation of the fluoroscopic evidence of increased or decreased irritability in the second and third portions of the duodenum should also be emphasized. In patients with an unstable duodenum one may see active peristalsis sweeping along the entire course of the duodenum in some cases and, in others, temporary stasis of barium in the second and third portions of the duodenum. Those cases showing temporary stasis in the distal portion of the duodenum are of particular interest. This transient stasis can be differentiated readily, as a rule, from the stasis of chronic duodenal ileus by the absence of the three fluoroscopic requirements for the latter diagnosis, viz., marked and persistent delay in emptying, definite dilatation of the duodenum, and antiperistalsis, these changes persisting when the patient is examined in different positions. Furthermore, the marked character of the symptoms of reverse peristalsis, which accompany a true duodenal ileus, afford further differentiation. As to the symptomatology of the unstable duodenum, the authors found epigastric discomfort in 51 per cent of their cases, frequently in association with the symptoms of an unstable or irritable colon. I should like to ask Drs. Friedenwald and Feldman whether they feel that the abnormal duodenal irritability constitutes an etiologic factor in the production of this common type of functional epigastric distress, which has usually been attributed to pylorospasm, and the conditions resulting from it.

DR. SARA M. JORDAN, Boston: It seems to me that what has been presented concerning the irritable duodenum applies also to what has in the past been called the irritable colon, and I wonder whether physicians haven't localized a little bit too definitely in the consideration of the irritable or unstable colon. Certainly evidences of the same symptoms that are here described as being caused by the irritable duodenum are found. Is it not perhaps then a question of irritability or instability—all terms are rather unsatisfactory—of the whole digestive tract, of which pylorospasm, this condition in the duodenum, and probably many other conditions in the rest of the small intestine not yet observed, plus the irritable condition in the colon, are all integral factors? I should like Dr. Friedenwald's and Dr. Feldman's opinion about that.

DR. MAURICE FELDMAN, Baltimore: Regarding Dr. Eggleston's remarks about the emptying time of the stomach, it was of interest to note that in this condition we did not observe an unusually rapid emptying. In the majority of cases the

stomach emptied in normal time, though in some instances it did empty more rapidly. Regarding Dr. Mateer's remarks about atropine and belladonna relieving symptoms, we have found these drugs to be of value. We have also found that on repeated examinations, which we have made in a number of instances, the irritable duodenum was not constantly present. The association of pylorospasm with irritable duodenum and irritable colon, as Drs. Mateer and Jordan referred to, was very striking. For instance, in our series of 100 cases there were forty-two cases of pylorospasm and fifty-one cases of irritable colon. It occurred to us as well that we were dealing not merely with a local duodenal involvement but perhaps with a more general condition.

CONGENITAL PSEUDARTHROSIS OF THE LEG

THREE CASES TREATED BY MASSIVE BONE GRAFT

PAUL C. COLONNA, M.D.

NEW YORK

The so-called congenital pseudarthrosis of the bones is an interesting and rather rare type of fracture. Wade¹ and Inglis² of Australia have made important contributions to this subject, but it is in the Italian and French medical literature that the greatest attention is devoted to it. In the American literature the most noteworthy contribution is by Henderson,³ who in 1923 called attention to the condition and in 1928 reported seven cases. It is not merely a fracture that fails to unite but a pathologic condition in the bone or bones, causing weakness and subsequent fracture. There have been reports of congenital pseudarthrosis of the clavicle, ulna and femur, but the bones of the leg are by far the most frequent site of the lesion.

The most satisfactory grouping would appear to be that of Codivilla,⁴ who has classified the cases under three headings: (1) those in which the usual anterior angular deformity exists without fracture, (2) those presenting a typical pseudarthrosis, and (3) those pseudarthrosis cases in which more or less loss of bony substance is accompanied by marked deformity.

Even before fracture has occurred, definite changes may be observed in the bone in which the fracture will subsequently occur. In this early phase of the condition there may be noted an anterior curving of the leg in its lower half. A superficial examination may confuse the deformity with that found in congenital absence of the fibula, although in the latter condition there is a definite pattern of deformity, consisting of a dimpled scar over the summit of the curve, a pes equinus and an absence of the fourth and fifth toes without any weakening of the integrity of the tibia. The roentgenographic appearance of the bones in these early cases of congenital pseudarthrosis before fracture has occurred presents a typical and characteristic picture. There can be noted an area or areas of rarefied bone, commencing in the region of the periosteum and extend-

ing partly or completely throughout the whole diameter of the bone in the region of its lower third. It suggests a local osteitis fibrosa cystica, and a certain amount of movement may be obtained in the bone at this point, even in the absence of fracture, owing to the impairment of the bony structure. There is this notable exception, however, that in true osteitis fibrosa cystica solid bony union following fracture is not delayed. Wade has reported four cases of congenital pseudarthrosis in which fracture was incomplete and the union very slow, there being no obvious callus thrown out. In one patient he reports that the union was soft after being splinted for a period of six years. If, however, fracture occurs, an increase of the deformity is most likely to develop.

The type most commonly seen is one in which a frank pseudarthrosis is present in both bones, with a characteristic angular deformity of the lower third of the leg, as shown in the accompanying illustrations. In the older cases the proximal bone ends are pointed and

the knee and foot and not be manifested at the apex of the curve. Codivilla and Henderson express the belief that the condition is probably due to a lack of embryonal development and assume that a congenital interference with the lack of development of the nutrient artery would explain it. Frattin⁷ believed that intra-uterine pressure due to amniotic cords or adhesions might be a factor.

All observers have commented on the fact that the general condition of these patients is usually good, and whatever may be the factor or factors it must be a local one. Codivilla states that the ample collateral blood supply in the upper portion of the leg is a factor in explaining why the congenital pseudarthrosis is always found in the lower half of the leg. However, Dillehunt and LeCocq⁸ report a case of this condition occurring in the upper third of the leg with a successful bony union following operation at the early age of 2½ years. This was the youngest patient in whom a successful outcome followed operation.

Fig. 1 (case 1)—A, condition before operation; B, preoperative appearance of pseudarthrosis; C, massive bone graft in position; D, appearance after solid bony union.

sclerosed while the distal fragments are frequently cup shaped with a varying degree of definite absorption between the bone ends, this space at operation being found filled with dense avascular tissue.

The Wassermann reaction was negative in the cases here reported, which fact coincides with the observations presented in other case reports.

There is considerable divergence of opinion regarding the etiology of the condition. Potel⁵ recognizes an initial curvature of the bone but feels from his cases that the bone is unaltered in structure. Roentgenograms of the cases reported by Wade show a definite cystic area at which fracture later occurred, and this finding may be noted in two of the cases here reported. Basseta⁶ has reported the examination of a fetus, 14 weeks old, presenting an early prefracture stage in which was found a blood clot between the ends of the bone consisting of a net of fibrin and a few stellar connective tissue cells. The effect of amniotic pressure in the development of this condition has been mentioned by several authors, but in opposition to this it would seem unlikely that the stigmas of pressure would be on

Kenwell⁹ has reported a case in which there was present also distinct blueness of the sclera and in which osteogenesis imperfecta was therefore considered. Roentgen examination and autopsy failed to reveal other fractures, but it was felt that the condition was a purely local manifestation and not a type of osteogenesis imperfecta. Inglis feels from a pathologic study of three cases that probably the centrally situated connective tissue represents marrow which was once normal and later became fibrotic, or that originally the medullary canal was occupied by connective tissue which was mainly fibrous, normal marrow being inconspicuous or absent.

The second case here reported was marked by an interesting feature. This boy was only 5 years of age when admitted to the Hospital for the Ruptured and Crippled, but even at that age he had been subjected to several unsuccessful attempts at bone grafting. While in the hospital several other unsuccessful attempts by the use of massive bone grafts were made. The

patient was discharged home between operations and at two separate times, about six months apart, fractured the tibia in its middle third on the sound leg. These fractures healed in the usual way with the presence of normal appearing callus and have remained healed to date. The normal bony structure was restored, while the dissolution and absorption of the transplanted graft on the affected leg continued. This, it would seem, is strong evidence in favor of the congenital pseudarthrosis being a local rather than a general manifestation. Therefore, the essential part of the pathologic condition seems to be a centrally situated connective tissue, which is partly fibrous and partly fibroblastic, occupying usually the lower third of one or both bones of the leg and initiated by a congenital lack of development of the nutrient artery.

TREATMENT

Of all the various procedures advanced for the treatment of this condition, operation is the only one that need be considered, and certain restrictions should be noted in the selection of cases and the type of operation

there was an obvious pseudarthrosis in the lower third of the leg. There was very little angulation present, but the curved and deformed fibula ends could be felt protruding just under the skin. There was no evidence of nerve injury. The patient was admitted, October 2, to the Orthopedic Service at Bellevue Hospital and was operated on, October 8. At operation the pseudarthrosis area was found filled with dense avascular connective tissue and the tibia and fibula bone ends were excised well above the area of pseudarthrosis. A large bone graft was removed from the opposite tibia and, after the right tibia was prepared for its reception, it was snugly placed in position and held there by kangaroo tendon. Bone chips were packed about the graft. No attempt was made to insert a graft into the fibula. The wound was closed without drainage and, in order to prevent undue tension on the graft, the foot was placed in an attitude of slight equinus. The postoperative course was uneventful and, six weeks after the original operation, definite evidences of bone repair could be noted in the roentgenograms. At this time the plaster was changed and an open zigzag tenotomy of the heel cord accomplished. Plaster was reapplied from the toes to the groin with the foot at right angles. Subsequent roentgenograms showed the process of bony union progressing satisfactorily, and the plaster support was removed from the leg six months after

Fig. 2 (case 2).—A and B, characteristic right angular deformity of the lower third of the leg; C, massive bone graft in place; D, normal healing of fracture of the opposite tibia coincident with absorption of the massive bone graft at the site of pseudarthrosis.

employed. Codivilla practiced the use of a cutaneous osteoperiosteal pedunculated graft, swung over from the sound side to the pseudarthrosis, and others have suggested shortening the leg sufficiently to obtain approximation and apposition of the fragments. However, the osteoperiosteal graft, the inlay method of bone grafting, or the massive bone grafting method proposed by Henderson would appear to be the methods of choice at the disposal of the operator. Whatever method has been pursued, failure has been frequent, and I myself have preferred the massive bone graft advocated by Henderson.

REPORT OF CASES

CASE 1 (fig. 1).—F. F., aged 11 years, seen at Bellevue Hospital in September 1929, complained of deformity of the right leg. The parents stated that the child's leg had been crippled since birth. There was no similar family history. The patient wore a brace on the leg until the age of 7, at which time the first operation for bone grafting was done. In all, the patient had had four unsuccessful attempts to produce union by bone graft operations, the last done about a year before. On examination the child was in good general condition, wearing a brace on the right leg, presenting marked shortening of this limb and being somewhat overweight. Blood chemistry studies were negative for any change in the blood calcium and phosphorus. The leg, on its anterior and lateral aspects, presented long healed scars as results of previous operations, and

operation. The patient was fitted with a leg brace accompanied by a long leather cuff. At the present time the patient is able to walk about without support but prefers to wear a brace when playing. Solid bony union, as shown, has resulted. CASE 2 (fig. 2).—J. G., a boy, aged 5 years, had fractured the right leg when he was an infant. After several unsuccessful attempts at healing by immobilization in plaster, open operations were done at another hospital and an attempt was made to produce union at the site of ununited fracture of the tibia and fibula in its lower third. As this was unsuccessful he was fitted with a brace, which he has worn from the time he was first seen at the clinic at the Hospital for the Ruptured and Crippled. Examination at that time showed marked deformity, as noted in figure 2. There was a long scar on the anterior aspect of the lower third of the leg, and another in the region of the achilles tendon as a result of previous operation. At the right angle angulation at the lower third there was a pseudarthrosis, and a roentgenogram showed nonunion of the right tibia and fibula at the junction of the lower third, with much loss of bone substance in the fibula, so that there was no contact of the fragments. The right tibia measured 8 3/4 inches (20.5 cm.) and the left 9 1/4 inches (23.5 cm.). The patient was admitted to the hospital for preliminary stretching and bone graft operation. At the first operation, Jan. 27, 1930, there was found to be a large amount of scar tissue around the point of pseudarthrosis. With bone forceps the bone was divided at about

1 inch above and 1 inch below the pseudarthrosis and completely removed, after which the angulation could be corrected. A large massive bone graft was taken from the anterior aspect of the left leg, removed with the aid of a motor saw, and held in place in the prepared bed in the opposite side by three kangaroo tendons. Another incision was made over the outer aspect of the leg on the right, and the two ends of the fibula were exposed, which were separated about $1\frac{1}{2}$ inches. A long sliver of bone was removed from the outer aspect of the fibula and the sharp end driven in the distal fragment and held by kangaroo tendon. Plaster was applied from the toes to the groin.

After an uneventful convalescence, subsequent roentgenograms showed no evidence of bone repair. Gradual absorption of the bone graft occurred.

At a second operation, October 6, an incision was made over the anterior aspect of the right leg and a definite pseudarthrosis could be demonstrated in the region corresponding to the distal end of the old graft to the proximal end of the tibia. The false joint was opened and thoroughly curetted. A sliding bone graft was made and the whole was held firmly with circular sutures of chromic catgut. One-half teaspoonful (2 cc) of calcium phosphate was placed about the site of fracture and

June 6, he was readmitted to the hospital because of the fracture of both bones of the leg on the left, at the junction of the upper and middle thirds, received by the patient jumping from the cupboard. The fragments were in good position and a plaster was applied. It was noted at this time that there was firm bony union at the site of the traumatic fracture received on this leg previously, and callus quickly developed about the site of the fracture of the upper third of the left leg.

The last report, March 15, 1934, shows that the boy is walking about with the aid of an artificial limb on the right and that the fractures of the left tibia have healed with solid bony union.

This case, therefore, is one which, in spite of repeated attempts at bone grafting in a child about the age of 6 years, resulted in failure in each case at the site of the congenital pseudarthrosis, while the opposite leg received two fractures, both of which healed normally. This would seem to support the view that the pseudarthrosis is produced by some local phenomenon, probably an interference with the normal circulation.

CASE 3 (fig. 3)—E L, a boy, aged 10 years, was seen, Nov. 5, 1932, on account of shortening and deformity of the

Fig 3 (case 3).—A, condition before operation, B, preoperative appearance of pseudarthrosis, C, massive bone graft in position; D, appearance after solid bony union

the wound closed in layers. Plaster was applied from the toes to the groin, the fragments being in good alignment.

Following this operation the wound broke down slightly and serum was discharged from the lower third of the leg with no evidence of infection. Clinically and from roentgenologic evidence, no union occurred following this operation. After a limited amount of weight bearing had been permitted, the child returned home in plaster.

The case was followed in the clinic for a long period and on Sept. 21, 1931, a third bone graft operation for congenital pseudarthrosis was performed, massive bone graft from the opposite leg being used for the ununited tibia. No attempt was made to treat the nonunion of the fibula at this time.

Satisfactory union did not follow this operation, and on November 14 the patient was admitted to the hospital because of a fracture of the tibia on the left side, which had been produced by a fall. The fragments were in good position. A plaster bandage was applied to this leg. It is interesting to note that, following the fracture on the opposite side, marked callus quickly developed and firm bony union rapidly followed. He continued to wear plaster and a brace on the right limb. An angulation deformity slowly developed at the site of the pseudarthrosis.

He was therefore admitted, May 4, 1932, and at his mother's request amputation was done below the knee. The wound healed by first intention and the patient was later fitted with a satisfactory artificial limb

left leg. The child's birth was apparently normal but shortly afterward the father noticed that the leg was deformed and diagnosis of fracture of the leg was made by a local physician. Reduction was accomplished and plaster applied, but the bones did not unite. The child had had five open operations with attempts to produce bony union of the left tibia and fibula. He had a scar over the anterior aspect of the opposite leg as a result of a previous bone graft being done.

On examination the boy presented deformity as noted in figure 3, with anterior angulation and pseudarthrosis of both bones in the lower third. The tibial fragments were not in contact. The length of the right tibia was $11\frac{1}{4}$ inches (28.5 cm.), and of the left was $7\frac{1}{4}$ inches (18 cm.). The child was fitted with a brace and walked about for the next few months.

Jan. 23, 1933, a massive bone graft operation was done. With the aid of rongeurs the pseudarthrosis was removed, embracing possibly 1 inch of the proximal and one-half inch of the distal fragment, and then with the aid of a motor saw a large bone graft was removed from the opposite tibia and placed in the prepared bed, being held securely by kangaroo tendon. The pseudarthrosis of the fibula was likewise removed, and bone chips were packed in the gap. The wound was closed in layers and plaster bandage applied from the toes to the groin. Post-operative roentgenograms show an increasing amount of callus formation with the bones in good alignment.

Six months after the operation there was firm solid bony union. The shortening on the affected side was treated by having the boy wear a patten.

In these three cases a massive bone graft was employed, all of which presented the typical angulation and deformity with forward bowing in the lower third of the leg and pseudarthrosis. All the children had been repeatedly operated on without success. This brings up the subject of the age when bone grafting should be attempted. Henderson in 1924 stated that "the response of these patients to surgery after puberty is much more satisfactory" and recommended careful improvement of the general health, local physical therapy and a walking caliper splint as preliminary to any operative procedure. In the three cases reported in which a massive bone graft was used, the patients had all been subjected to three or more previous bone grafting operations with subsequent failure, and, in the second case, bony union was never obtained, amputation finally being done at the insistence of the mother. In the two other cases successful union followed, one child being 11 years of age and the other 10. It is felt that subjecting a patient under the age of 8 years to this type of operation is most likely to result in failure of solid union and that, up to this age, support with plaster or a brace and general hygienic treatment would be the wiser course to pursue.

SUMMARY

1. The condition of congenital pseudarthrosis has been rarely reported in the American literature.
2. The condition of congenital pseudarthrosis of the leg would appear to be a local rather than a general cause and to occur usually in the lower third of the leg.
3. The bone or bones involved present a characteristic roentgenographic appearance of a cystic formation, which pathologic condition precedes fracture and somewhat resembles a localized osteitis fibrosa cystica. The deformity is present at birth and fracture occurs either at or shortly after birth, hardly ever healing spontaneously.
4. Under the age of 8 years, operative treatment is not indicated and the chances for success by operation increase with the age of the patient.
5. The massive bone graft technic, as recommended by Henderson some years ago, was the method employed in the three cases here reported, in two of which (66⅔ per cent) bony union was obtained.

59 East Fifty-Fourth Street.

ABSTRACT OF DISCUSSION

DR. PHILIP LEWIN, Chicago: This is a very interesting and baffling condition. The pathologic changes are evidently purely local and they are undoubtedly predetermined by a peculiar embryologic twist, which permits the interposition of soft tissue. The literature on this subject is not large. The most important articles in English were written by Henderson and Wade. There is evidently a local metabolic bone lesion the nature of which may be cystic. The bowing in these cases may be primary or secondary. The importance of the nutrient artery in some cases is considerable. Dr. Colonna's results would indicate that his method of treatment is worthy of further trial. It is my belief that, as further progress is made in the treatment of this condition, the age at which operation will be indicated will be lowered. The important points are wide excision of pseudarthritic areas and the application of a double-wedge graft with osteoperiosteal and chip graft and some bone marrow.

DR. PAUL CRENSHAW COLONNA, New York: I should like to agree with Dr. Lewin that with more general use of the massive bone graft and improvement in technic the age period for attaining union may be lowered. I hope it will prove to be so. I think it is interesting, though, that the cases that have defied attempts at successful bone grafts have all been in this lower age group.

REGIONAL (TERMINAL) ILEITIS: ITS ROENTGEN DIAGNOSIS

JOHN L. KANTOR, M.D.

NEW YORK

This is a preliminary communication based on a review of six private cases¹ that came to surgical exploration in the last six years. In four of these the operation was performed by Dr. A. A. Berg and the pathologic examination was made by Dr. Paul Klemperer at the Mount Sinai Hospital. All these cases were finally diagnosed nonspecific ulcerative granulomatous inflammation of the terminal ileum according to the criteria presented by Crohn and his collaborators in 1932.² In the remaining cases operation was done elsewhere and before the term "regional (terminal) ileitis" was introduced in the literature. Nevertheless, these descriptions also agree on the presence of ileac thickening and ulceration, and on the absence of new

Fig. 1.—Normal ileocecal filling. Film taken five hours after opaque meal with patient in the prone position. There is no filling defect anywhere in the course of the barium column from its "tail" in the terminal ileum to its "head" at the splenic flexure of the colon. Note particularly the position, shape and general symmetry of the terminal loop of ileum.

growth, tuberculosis and other known specific inflammation or tumefaction. It therefore seems fair to assume, at least for the purpose of this preliminary communication, that a homogeneous group of cases is being dealt with. A summary of the chief clinical features in these patients is presented in table 1.

Read before the Section on Gastro-Enterology and Proctology at the Eighty-Fifth Annual Session of the American Medical Association, Cleveland, June 13, 1934.

1. In all the cases here described, the disease involved only the terminal ileum. There is increasing evidence that other parts of the alimentary tract may be affected (Harris, Bell and Brunn,¹² Crohn and his associates²).

ROENTGEN INDICATIONS OF REGIONAL ILEITIS

The present status of roentgenology of the small intestine may be compared to that of the stomach twenty years ago. Despite the contribution of Mills,³ Cole⁴ and his collaborators, Case, Soper,⁵ Lawrason Brown, Ritvo,⁶ Raiford,⁷ Bloom,⁸ and Goldfarb⁹ in this country, it is probably true that this branch of gastro-intestinal

ROENTGEN INDICATIONS IN REGIONAL ILEITIS

Abnormalities may be found either in the colon or in the ileum (table 2). The changes in the colon are usually the result of spasm secondary to the ileac involvement. The situation in this regard is similar to the Stierlin¹⁰ filling

roentgen diagnosis is not very widely practiced; hence the following description of the technic used by me may not be out of place:

1. The standard opaque meal is employed. It is administered on an empty stomach.
2. All roentgenograms are made with the patient prone, the rays being directed dorsoventrally. This posture is preferred to the erect position because in the former the ileac loops are more widely separated.
3. Observations are made at hourly intervals from the period just before the cecum fills to the normal period of ileac emptying. This means from three to nine hours after the ingestion of the opaque meal.
4. The patient is allowed to take an ordinary meal as soon as the stomach is seen to be empty. This takes place normally five hours after the barium meal.

spasm of the cecum or cecocolon the changes are not constant but intermittent. Furthermore, the opaque enema usually suffices to fill out the involved areas in normal fashion.

On the other hand, the colon may be actually involved by the disease process in the adjacent ileum, as by adhesion or fistula formation. In such instances a fixed

deformity results, most commonly affecting the inner (mesial) aspect of the large intestine.

In the ileum are found the most important changes. The present series of cases showed the following:

1. Filling defect. There is a constant defect in the filling of the terminal small intestine. This is manifested in all observations and offers a striking contrast to the familiar picture of the final loop of ileum as it rises out of the pelvis to enter the ileocecal valve

TABLE 2.—Roentgen Changes in “Regional Ileitis”

“String sign”.....	?	+	0	+	+	+

(fig. 1). The extent of this ileae filling defect depends on the extent of the stenotic process in the small intestine.

2. In three of the six cases the ileum proximal to the filling defect seemed abnormal in contour. The involved loops appeared irregular in shape, or else the very last segment of ileum showed a peculiar taper

point. In some cases this taper point became continuous with the “string sign” to be described.

3. Actual obstruction was present in two cases. This was manifested by stasis in the ileum nine hours or more after the opaque meal and by dilatation of the loops proximal to the filling defect.

4. Perhaps the most striking finding is the “string sign” (figs. 2, 3 and 4), a name borrowed from A. W. Crane. This is a thin, slightly irregular linear shadow suggesting a cotton string in appearance and extending more or less continuously from the region of the last visualized loop of ileum through the entire extent of the filling defect and ending at the ileocecal valve. It represents the attenuated barium filling of the greatly contracted intestinal lumen. A characteristic “string sign” is apparent in the illustration of the original article by Crohn and his collaborators,² as well as in the illustrations of Harris, Bell and Brunn¹² and of Goldfarb.⁹ Multiple or branched “string signs” may be attributed to multiple areas of involvement or to fistula formation (fig. 4).

DIFFERENTIAL DIAGNOSIS

Although easy enough to recognize when once seen, it may be possible to confuse the “string sign” with a filled appendix dipping into the pelvis and perhaps with the line of the right sacro-iliae synchondrosis. The

Fig. 5.—Differential diagnosis of regional ileitis. Sarcoma of ileum. Film six hours after opaque meal. Note atypical course of attenuated terminal ileum. The impression given is that of a loop of bowel stretched over an eccentrically located tumor. Such an appearance has not been observed in the cases of regional ileitis seen to date.

appendix shadow is likely to be more homogeneous in density and its outline more uniform than that of the “string sign.” The synchondrosis may be identified by careful comparison with the shadow of the opposite (left) side.

The “string sign” may also have to be differentiated from the streak-like filling of abnormally contracted

12. Harris, F. J.; Bell, G. H. and Brunn, H.: Chronic Cicatrizing Enteritis, Surg., Gynec. & Obst. 57: 637-645 (Nov.) 1933.

(spastic) segments of small intestine. In the case of the latter the lumen is wider, the shadow denser and the outline smoother, and, more important still, the location of these loops may vary from one exposure to another because of the freer mobility of such bowel segments. It is characteristic of regional ileitis that the "string sign" remains hour after hour and even day after day in practically the same relative location in the right lower quadrant.

When it comes to pathologic lesions, it must be noted that regional ileitis is but one of several stenotic lesions that may present a picture similar to, if not identical with, the "string sign." Circumscribed tuberculomas of the terminal ileum have been described with illustrations showing a similar thin streak or streaks of barium by Stierlin and Chaoul¹⁰ and by Schilling and Sametnik.¹³ Yet the last named authors present a second case, almost identical with their first, in which, much to their surprise, they failed to find evidence of tuberculosis or new growth and seemed to be dealing with an instance of what might now be called regional ileitis. Stenosing sarcomas of the terminal ileum have been described by Raiford and by Bagnaresi.¹⁴ Talia¹⁵ specifically states that in a case of sarcoma there was a thin strip of barium joining the terminal loop of ileum with the ileocecal valve. A similar instance has come under my observation (fig. 5). Finally, according to Talia, syphilis of the terminal ileum may present exactly the same picture.

In view of these facts one must conclude that, although the "string sign" is not necessarily pathognomonic of regional ileitis, one must always bear this disease in mind when a "string sign" is present.

REPORT OF CASE

In the following case (case 6 of the present series), the diagnosis was made before operation:

A man, aged 30, married, had noticed increased fatigue for ten years. Four years before admission he had a perianal abscess of undetermined type, resulting in a fistula, which was excised. Three years before, onset of three watery stools daily occurred. For two years there had been abdominal distress, and for one year weight loss, fever (maximum 104, average 100-101), anorexia, and blood in the stools. Eight months before he had abdominal cramps for one week, followed by temporary improvement. Four months before there was a recurrence of diarrhea, cramps and fever, and onset of vomiting.

On physical examination, May 12, 1933, the patient was of sthenic habitus, appeared acutely ill, and was pale. He weighed 142 pounds (64.4 Kg.) (ideal weight 172 pounds, 78 Kg.). The lips were dry and cracked and there was slight gingivitis present. The chest was normal. The abdomen was distended and tense; borborygmi were present; there was visible erection of the intestine in the lower midportion of the abdomen. No mass was found. The rectum was normal. The blood pressure was 102 systolic, 80 diastolic; the pulse, 120 and the temperature, 100.2 F. (rectal).

Routine laboratory tests showed hemoglobin, 69 per cent (Sahli, normal 80 per cent). Albumin, hyaline and granular casts were present in the urine; indican was increased. The fasting stomach was empty on aspiration. A test meal was not done.

On roentgen examination, May 13, the stomach and duodenum filled normally.

Three hours after eating, the jejunal and ileac loops were markedly dilated. The cecum was beginning to fill faintly, but the terminal ileum was not visualized.

Four hours after eating, there was one stool. The cecocolon was faintly filled. The jejunum-ileum was still dilated.

Five hours after eating, there was a minute residue still present in the stomach. The colon filled faintly to the distal transverse. The jejunum-ileum was still dilated. A beginning "string sign" was noted.

Six and a half hours after eating, there were two stools. The stomach was empty. The colon was filled to the rectum. The ileum was unchanged. The "string sign" was more marked (fig. 2).

Seven and a half hours after eating, there were three stools. The colon was unchanged and the ileac loops were still dilated; the terminal ileum still showed the filling defect; the "string sign" was still present (fig. 3).

Eight and a half hours after eating, there were four stools, with the same conditions as before except that the "string sign" was not visible.

Twenty-four hours after eating, there were four stools. The cecum was contracted and the colon filled normally from the midascending position to the rectum. The ileum still showed a faint trace of barium.

Forty-eight hours after eating there were seven stools. The colon filled from the hepatic region to the rectum. The ileum was empty.

Seventy-two hours after eating, there were twelve stools. The colon was empty.

Of the opaque enema, 42 ounces was required to fill the colon to the cecum (normal amount 38 ounces). The cecal tip appeared contracted with a budlike protrusion on the mesial surface, three-eighths inch in diameter.

The diagnosis was regional ileitis; the deformity of the cecum was due either to spasm or to involvement in the inflammatory process.

Radical surgical therapy was recommended.

May 29, Dr. A. A. Berg did a resection of the terminal ileum and proximal cecocolon for typical terminal ileitis, with anastomosis of the ileum to the ascending colon.

The pathologic examination was made by Dr. Paul Klemperer. The specimen consisted of a loop of terminal ileum, measuring 23 cm., and 5 cm. of cecum and ascending colon with the appendix. The wall of the ileum was markedly thickened, the serosa was reddened, the fat tissue was penetrated by grayish white fibrous strands. When the specimen was opened, the terminal 8 cm. of ileum showed a marked stenosis. The lumen was narrowed to the thickness of a pencil. The mucosa was thickened and in places consisted of flat polypi. Along the mesenteric insertion there were longitudinal ulcerations, and there the thickening and contraction were most marked. The mucosa showed, in addition, irregularly outlined shallow and deeper ulcerations. It was grayish, and small fragments of a membrane could be pulled off. The underlying submucosa and muscularis were markedly thickened. The latter showed grayish white streaks.

Proximal to the area just described there was a widening of the lumen; the muscular coat was markedly hypertrophic. The mucosa was thickened and showed a few serpyiginous shallow ulcerations. Their base was grayish and the edges were red. At a distance of 8 cm. from the proximal termination of the severest involvement there was an almost circular ring, about 1 cm. in width, in which the mucosa was involved in a manner similar to that previously described. Proximal to this circumferential lesion there was a dilatation of the intestine with a few similar scattered ulcerative lesions and then followed again a circular involvement. Still proximal to that, the mucosa was slightly thickened and reddened, but no ulcerations were present.

At a distance of 2 cm. from the ileocecal ring, one of the ulcerations had penetrated all the coats of the intestine up to the serosa. The opening of the fistula was covered by the appendix, which had become adherent with a thickened mesenterium. The appendix at this point was also markedly

infiltrated. The mucosa of the appendix was granular and thickened.

Within the mesentery of the ileum there were a number of hyperplastic lymph nodes. The cecum and ascending colon showed only a few mucosal hemorrhages. There were no other changes. The intestinal lesions ended sharply at the ileocecal valve.

The pathologic diagnosis was nonspecific ulcerative granulomatous inflammation of the terminal ileum and appendix, with fistula.

Following the operation the patient made a smooth recovery. May 7, 1934, the general condition was excellent. The weight was 195 pounds (88.5 Kg.). The bowels moved twice a day normally.

SUMMARY

1. In obscure cases of apparent colitis a roentgen study of the small intestine may reveal the presence of a terminal (regional) ileitis.

2. The roentgen study of the small intestine is based on the careful observation of a progress meal from the time the cecum begins to fill to the time the ileum should normally be empty.

3. The chief roentgen signs in regional ileitis affect the colon and the terminal ileum. The changes in the colon, however, are likely to be reflex in nature.

4. The chief changes in the ileum are:

(a) Filling defect just proximal to the cecum.

(b) Abnormality in contour of the last filled loop of ileum.

(c) Dilatation of ileac loops just proximal to the lesion.

(d) A "string sign" representing the actual lesion.

5. The "string sign," though characteristic, is not pathognomonic of ileitis. It may be present in other stenosing processes in this region. When present, however, the diagnosis of terminal ileitis must be given consideration.

ABSTRACT OF DISCUSSION

DR. HARRY M. WEBER, Rochester, Minn.: Dr. Kantor has described the roentgenographic evidence for the narrowing and the distortion of the terminal ileum, two of the most conspicuous and significant anatomic features of the disease now quite generally known as terminal ileitis. He endows the term "string sign," which he revives, with a new significance, as here actual organic disease is responsible for the roentgenologic appearances of which the term is vividly descriptive. A different but hardly less familiar method of visualizing the terminal ileal coils might not inappropriately be recommended here, not to replace but to supplement and serve as a check on the information elicited by the method just described. It is the primary roentgenologic method of studying these segments at the Mayo Clinic, where they are examined as an integral part of investigation of the colon, in much the same sense as examination of the duodenum is a part of examination of the stomach. Under roentgenoscopic control the terminal ileum is filled to a desired extent with opaque suspension by reflux through the ileocecal orifice. The patient is then permitted to relieve the colon of the bulk of contrast fluid it contains by defecation. The ileum normally remains more or less completely filled with contrast fluid and rests at a level higher in the abdominal cavity than at the four and six hour periods after ingestion of the opaque meal, making it more accessible for screen-controlled manipulation. More important still from the standpoint of eliciting roentgenologic evidence of relatively early pathologic change expressed on the mucosal surface, there is a minimal mixture of contrast substance with nonopaque intestinal content, since the latter has been reduced to a minimum with the preparation of the large intestine for its examination. It is felt that in this way the terminal ileum is made

almost as readily accessible for roentgenologic examination as are the stomach and large intestine, and the diagnostic results are expected to be as accurate and reliable; hence it does not seem unreasonable to demand a diagnosis of terminal ileitis from the roentgenologic examination before that stage in its development when these extensive changes have already taken place. Nor is it unreasonable to suspect that at earlier stages the disease might be amenable to less radical surgical therapeutic measures than have been found necessary up to the present time. It is entirely possible, indeed, that in early stages the disease might be arrested, even eliminated, by nonsurgical management.

DR. JAMES T. CASE, Chicago: The technic of examination of the small intestine in its terminal portion is interesting. It matters little whether one decides on using the opaque enema method or the barium meal followed through. Some will become more expert in one and others in the other. I myself prefer to use a combination of the two methods. I like to give a progress meal and follow it through. I advocate the use of frequent observations of the small bowel. In order to do that, the meal should begin early in the day. The practice of beginning meals at 1 o'clock or later in the day does not permit sufficiently frequent observations of the bowel between the fifth and ninth hours, unless one behaves unusually in habits of working hours. Barium can be taken at the ordinary breakfast in the morning, and the patient can be seen for the first time around 11 o'clock, and from then on the study should be done fluoroscopically with the patient prone on the fluoroscopic table, and with manipulation under the fluoroscopic screen. Films can be exposed under the screen at the time of fluoroscopy, which will be more illuminating than having the films made in the reverse position. It is true that one can use the opaque enema for studying the terminal ileum. I too make it a habit to give the enema until the lower coils of the ileum are visualized. That is routine, and the filling of the sigmoid by the opaque material often lifts the small intestine out of the true pelvis into a place where it can be manipulated. Manipulation under the fluoroscopic screen is an important adjunct to the roentgen study of the digestive tract. Another method is to inflate the bowel with air after the introduction of thorium dioxide or barium sulphate sufficiently to reach the terminal ileum, a minimum amount of opaque material being used; but inflating the bowel with air is rather distressing and I do not use it very often. I should like to call attention to the herring-bone appearance of the small intestine above the dilated loops. Sometimes this is the first indication of an organic lesion in the terminal ileum. As a source of possible error, I would mention that there may be found an empty loop of terminal ileum where it lies over the iliopectineal line, especially if the patient is observed prone. I should like to commend Dr. Kantor's remarks. I appreciate what he said about some doctors being "addicted" to the examination of the colon by enema alone; there are many lesions of the colon, some of them organic, which can be determined only by watching the progress of opaque material.

DR. ANTHONY BASSLER, New York: I want to express appreciation to Dr. Cohn for bringing this subject forward again, and to Dr. Kantor, and I suggest that his demonstration in the Scientific Exhibit be seen. I feel that the atonies, the spasms, the hyperplasias and the granulomas in the intestinal canal need a great deal more study than they have had so far. I don't think that they are going to be entirely understood until biologic investigation of the intestinal canal becomes a routine procedure. Perhaps some may remember that I was the first to suggest the use of the x-rays in granulomatous processes. I treated not a few of them and have seen most favorable results from the rather simple method of the therapeutic use of the x-rays with the proper type of machine. The lesion of ileitis is really a local irritation, a low grade inflammation of the mucosa. It begins in the mucosa and in all probability is due to certain of the anaerobic organisms that can be found in the intestinal canal, of which there are about eight genus types, and my observations have suggested that they are capable of producing the condition. The pathology is one of proliferation of the hematopoietic cells and mainly proliferation and irritation of the somatic cells of the intestinal wall. The granulomatous processes of syphilis and tuberculosis,

the two outstanding granulomatous processes, are due to infections. The others that occur in the intestines and rectum I feel are also due to infection, also anaerobic bacterial in type. Making allowance for the difference in the anatomy and physiology of the intestinal mucosa and the skin, in which low grade infections are common, that probably is the reason why the therapeutic doses of x-rays have been helpful in the granulomatous processes. Since the infection is a closed one, as compared with similar infections of the skin, surgical therapy may become necessary.

DR. B. B. CROHN, New York: When I first published a paper on ileitis in 1932 I had fourteen cases; to date I have had forty-two cases. I have added twenty-eight cases in two years, and that will give an idea that ileitis is not an unusual finding and that its distribution is wide, as evidenced by the fact that cases are coming from all parts of the United States. I had a letter from Amsterdam, Netherlands, stating that cases were being found over there, too. The disease is one of youth; the incidence ranges from 4½ years of age (the youngest) to 30 or 40. A case is rarely seen above the age of 30. I am grateful to Dr. Kantor for naming this manifestation in the ileum the "string sign." It is a fitting term. The string sign is absolutely characteristic. I hesitate to say it is pathognomonic, though I think it is, because in the differential diagnosis of other conditions that may create the same sign I can think of sarcoma of the small intestine, nearly always multiple, and of Hodgkin's disease, affecting the mucosa by secondary involvement, which does not give a picture similar to the string sign. Cases run for years with some diarrhea, slight elevation of temperature and slow loss of weight. Many of them are lost as cases of psychoneurosis, because the nervous manifestations are common and the diarrhea insignificant. One finally discovers this radiographic sign and the diagnosis becomes obvious. In the original conception the disease was considered to be limited to the terminal ileum, but soon, thanks to Dr. Bargen's suggestion, the possibility of involvement of the upper ileum was suspected and soon cases were found in which the terminal and the upper ileum were involved. In an involvement of the upper ileum itself it is almost invariable that the terminal ileum also is involved, and any surgical resection that fails to remove the terminal ileum is very likely to meet with failure. In twenty-five cases picked to show the segmental distribution of the disease, the terminal ileum was almost always involved. The disease transcended the ileocecal valve in only one case. It had passed over into the cecum. After Harris's publication (from San Francisco), I was on the lookout for cases of high intestinal involvement, and soon ran into cases involving more extensive segments of the ileum, and to cases involving the whole ileum and even the jejunum. I have observed four atypical cases. These cases were seen at exploratory laparotomy. The terminal ileum was seen as absolutely rigid as a hose pipe, but there was massive involvement of segments of the transverse colon and descending colon, and also in certain instances of the ascending colon. The patients were too sick for resection, with temperatures of 103 and 104 F. These cases have gone on to spontaneous recovery. I cannot classify them as ileitis. The patients had no diarrhea but only two or three movements a day. It may be necessary to revise or add to the present notion of ileitis and colitis by recognizing a combined disease in which the terminal ileum and segments of the colon are involved.

DR. JOHN L. KANTOR, New York: I am grateful to Dr. Weber for the term "twisted cord" appearance as an alternative to the "string sign" nomenclature for the characteristic x-ray appearance. I wholly agree that, by using the colon enema in such a way as to fill the terminal ileum deliberately, much valuable information can be gained. To Dr. Case all owe a debt of gratitude for his pioneer work in the radiology of the colon. He made a good suggestion, namely, to start the examination early in the day so as to give enough time for study of the small intestine. Dr. Bassler quite properly pointed out that these are the end results of the lesions of the disease and that operations, for example, may not be the whole story in the way of therapy. Dr. Crohn deserves credit, as always, for calling attention to this disease, and it is gratifying to know that he has accepted these roentgen observations.

THE EFFECT OF VITAMIN A ON THE COMMON COLD

GERALD S. SHIBLEY, M.D.
AND
TOM D. SPIES, M.D.
CLEVELAND

Vitamin A is often called the anti-infective vitamin, and this anti-infective value is believed to be especially operative in the prevention of bacterial invasion of mucous membranes.¹ Because of this alleged protective value, substances containing this vitamin are being advocated extensively, without adequate experimental proof, for prophylaxis against the common cold. The common cold and its complications are of such great importance that it seemed desirable to determine whether or not the addition of vitamin A to the diet has any effect on the prevention, duration and severity of the disease. In the present communication we are reporting the results of such a study. Recently, somewhat less detailed and shorter studies have been reported in infants by Wright² and by Hess and his co-workers.³ Our own investigation has been limited to observations made on young adults.

From a practical standpoint, it seemed far more important to compare individuals on average diets supplemented by vitamin A with those on such diets alone than to attempt the almost impossible and far less useful comparison between individuals receiving adequate amounts of the vitamin and those on an imposed deficiency diet. Although the average American dietary contains an appreciable amount of vitamin A, it is quite possible that at times there may be a deficiency of small though definite subclinical proportions.⁴ Our aim has been to determine whether the addition of substantial amounts of vitamin A to average, perhaps somewhat deficient, diets would significantly influence the incidence, severity and duration of colds.

METHODS

Material.—At the beginning of the study the experimental group consisted of 241 adult volunteers. Of these, 143 were first and second year students in the Western Reserve University School of Medicine; sixty were first and second year students in the School of Nursing, fifteen were head nurses in the Lakeside Hospital, and twenty-three were members of the profes-

sional and technical staff of the hospital. About one third were women. The mean age was 24 years. At the end of the experiment the total number had fallen to 211.

Duration of Experiment.—Vitamin administration was begun in the latter part of January 1933 and was discontinued the first week of March 1934. The period of observation of colds began Feb. 4, 1933, and ended March 3, 1934, a total of fifty-six weeks.

Administration of Vitamins.—Vitamin A was given in the form of halibut liver oil.⁵ In view of the well

recognized fact that vitamin A is stored for some time in the tissues of animals and man, the material was given for greater convenience weekly rather than daily. Each weekly dose contained 200,000 international units (I. U.) of vitamin A and definitely exceeded the usual amount taken in a week when the vitamin is prescribed on the customary daily basis. In addition, each dose of halibut liver oil contained 4,000 international units of vitamin D.

Although the fact of storage is generally accepted, it was considered necessary to demonstrate experimentally in animals that vitamin A in sufficient amounts could be given at weekly intervals and still protect against manifestations of deficiency. For this purpose twenty-five white albino rats between the ages of 3 and 4 weeks, weighing from 40 to 50 Gm., were selected. The dosage of vitamins given to these rats was proportionate by body weight to the amount administered to the volunteers.

The rats were divided equally into five groups and all were fed Sherman's basal vitamin A-free diet⁶ ad libitum throughout the period of observation. A weigh-back on their diets was made daily. Animals in group 1 received no vitamin A, but each was given 0.5 international unit of vitamin D daily. Each animal in group 2 received a daily supplement of 15 international units of vitamin A and 0.5 international unit of vitamin D. Each rat in group 3 received a single weekly dose of 105 international units of vitamin A and 3.5 international units of vitamin D. In group 4 each animal received at two week intervals a dose of 210 units of vitamin A and 7 units of vitamin D. In group 5 each rat was given a single dose, at intervals of three weeks, of 315 units of vitamin A and 10.5 units of vitamin D. The vitamin supplement was dropped

directly into the mouth of each animal in such a fashion as to insure his receiving the entire amount. All animals were weighed every other day and they were examined at frequent intervals for any manifestations of disease.

By the end of the sixth week the rats in group 1 (those receiving no vitamin A) failed to maintain their initial gain in weight and began to eat less than previously. Two weeks later they had definite manifestations of vitamin A deficiency characterized by a generally unkempt appearance, circumorbital swelling, and infection of the eyes; by this time they had lost 30 per cent of their body weight and were eating only one half of the maximum basal diet they had taken previously. All animals in the other four groups continued to grow and to gain weight normally and at the end of the eighth week, when the experiment was terminated, showed no evidence of disease.

Selection of Groups.—The volunteers were divided into groups A, B and C. Both random sampling, to avoid the error arising from an unequal distribution of so-called cold susceptibles, and probable continued equality of groups were sought for by placing individuals in the three groups as follows: On the basis of scholastic standing and beginning with the highest student in a given class, individuals were assigned in turn to each group; i. e., first man in his class to group A, second man to B, third to C, fourth to A again and so on. The remaining thirty-eight were selected at random by alphabetical draw. The groups at the beginning contained: A, seventy-six; B, eighty-three; C, eighty-two. At the end of the experiment they numbered respectively sixty-seven, seventy-one and seventy-three. Group A received halibut liver oil. The other two were controls: one, group B, was given the viosterol equivalent of the halibut liver oil administered to group A, and the other, group C, received plain maize oil. Special efforts were made to have individuals taking part in the experiment ignorant of their group in order to prevent a prejudiced point of view. To aid

Fig. 2—Incidence rate of colds in test and control groups. The figure shows the weekly percentage incidence averaged for successive four week periods.

in this, the material was well disguised in a small amount of tomato juice (which contains only a little vitamin A).

Collection of Data.—At the beginning of the experiment a careful presentation of the problem and a detailed discussion of the character of colds and their symptoms was entered into with the entire group. Although all taking part had a medical point of view, each factor in detail was clearly defined. Such conferences were renewed from time to time throughout the experiment. For actual collection of data regarding

⁵ This experiment was made possible through the courtesy of Dr. C. E. Bills of Mead Johnson & Co., who placed large quantities of halibut liver oil and viosterol at our disposal.

7. The test group was made slightly smaller to reduce cost.

respiratory infections, cards (fig. 1) were sent out each Monday for the week immediately preceding. Whenever symptoms were reported, the individual was seen personally and all details were carefully checked.

Definition of Common Cold.—For this study we have included mild to moderately severe infections of the upper respiratory tract of the typical type usually called "common cold," characterized by definite coryza, rhinitis and nasopharyngitis. We have not included simple follicular pharyngitis, follicular tonsillitis, influenza (so classified on the basis of severe constitutional reaction with prostration and minimal involvement of the upper respiratory tract), hay fever, and short respiratory attacks of a duration of twenty-four hours or less.

RESULTS

Effect of Vitamin A Supplement on Incidence of Colds.—In analyzing the incidence of colds in the vitamin A group and in the controls, the problem has been approached from two angles. First, a comparison has been made of the weekly incidence rates in the groups as a whole, all participants in the experiment being used, and, second, comparisons have been made of the individual attack rate in those subjects only who completed the whole fifty-six weeks period of study. As noted, the three groups did not remain at full strength. The drops in groups A, B and C were respectively seventy-six to sixty-seven, eighty-three to seventy-one, and eighty-two to seventy-three, or a total drop from 241 to 211. This loss was fairly evenly scattered throughout the experimental period.

The attack rate was calculated on the basis of the number of colds per hundred individuals weekly. The results are shown graphically in figure 2, in which the incidence rate is charted as the weekly percentage incidence averaged for successive periods of four weeks. The total number of colds entering into this analysis is 753. Examination of this figure shows that the three curves are essentially identical. In other words, no evidence is forthcoming from these data that supplemental vitamin A has any influence on the incidence rate of colds. The curve is of interest in that it shows the sharp epidemic peaks noted by Townsend⁸ and other observers in the early fall and winter months.

In order to compare the average individual incidence of colds in the vitamin A group with that in the control groups, it was necessary to include only individuals who participated in the experiment throughout the entire period of fifty-six weeks and whose final colds were complete when we terminated the study. The results of the analysis showed the average number of colds per individual to be: group A, 3.42 ± 0.14 ; group B, 3.56 ± 0.13 , and group C, 3.06 ± 0.15 . When all who completed the experiment are included, with an increase in the number of individuals respectively in the three groups of nine, eight and five, the average individual incidence is: group A, 3.41; group B, 3.53, and group C, 3.25. This is further clean-cut evidence that supplementary vitamin A in excess of that contained in the usual dietary has no influence on the incidence of colds. These results are in entire harmony with the observations of Hess and his co-workers³ and of Wright.²

Influence of Vitamin A Supplement on Severity of Colds.—In a disorder as mild as the common cold, determination of relative severity is a difficult task. In attempting this, previous observers have used some or

all of the following standards: fever, malaise, absence from school or work, going to bed, complications and duration. The following three criteria have been selected arbitrarily for this study: (1) aching or malaise, (2) fever at onset as recorded by a thermometer, (3) going to bed. The factor of duration will be considered separately and in general is not necessarily related to severity of infection. When a cold was reported with one only of the three criteria noted, it was designated +, the presence of any two of these led to the designation ++, and when all three were present the cold was called +++.

Of the total of 753 colds reported, 158, or 21 per cent, were classified as + to ++++. The distribution of these relatively severe colds in the groups is shown in table 1. It will be noted that their incidence is essentially identical in the three groups. This is true not only of severe colds as a whole but also of the three individual categories. Although the number of these relatively severe colds is comparatively small, their strikingly similar incidence in the three groups points strongly to the probability that supplementary feeding of vitamin A leads to no significant reduction of colds of relatively severe types.

TABLE 1—Distribution of Relatively Severe Colds*

Severity of Cold	Number of Colds		
	Group A Halibut Liver Oil	Group B Vioosterol Control	Group C No Vitamin

++	18	15	17
+++	8	10	8
Totals	55	51	52

* Severity determined on basis of presence of (a) aching or malaise; (b) fever, with thermometer, (c) going to bed; + indicates any one of foregoing, ++ any two, and +++ all.

Effect of Vitamin A Supplement on Duration of Colds.—Precise information regarding the duration of colds is notoriously difficult to secure. Some individuals consider that their colds have terminated as soon as their relatively acute symptoms are over, others have a substrate of mild chronic nasopharyngitis, and still others have a definite background of chronic sinusitis. It took us several weeks at the beginning of the study to realize our difficulties and to educate our experimental subjects in the matter of accurate reporting of termination.

Our criteria for determination of duration were: In the case of subjects who have had a background of chronic nasopharyngitis or sinusitis, a new acute infection was considered terminated at the point when, in the opinion of the subject, it had receded to the approximate level of the usual chronic symptoms. Each decision in this group generally required repeated careful consultation with the individual concerned. The numbers of these subjects in each group were respectively nine, nine and ten. One point that was most difficult to settle in such individuals was the differentiation between mild exacerbations of a chronic condition and true new infections. For all others in the experiment, a cold was considered as ended when all symptoms had completely disappeared. Such symptoms often arose from secondary manifestations as purulent nasopharyngitis or sinusitis, laryngitis, tracheitis or bronchitis. The mean duration of colds in the control groups with the exception to be noted below was 12.5 days. This

is 2.5 days shorter than the duration of colds in students as reported by Doull.⁹ It is possible that this difference may be accounted for on the basis of our exclusion of symptoms of a definitely chronic nature from the duration of acute colds.

As noted, supplementary feeding with vitamin A has had no influence on the incidence or severity of colds. The results are unequivocal. In the matter of duration, the experimental data have been somewhat more difficult of interpretation. When the results were first analyzed, it became apparent at once that the colds in

the vitamin A group were consistently shorter than those in the two control groups. When all completed colds (732) were included, the mean average duration was found to be: group A, 9.59 ± 0.12 ; group B, 11.07 ± 0.22 , and group C, 12.51 ± 0.23 .

These preliminary figures were taken to Dr. G. E. Harmon of the Department of Hygiene and Bacteriology for examination and he reported that they were significant statistically, provided duration had been determined on the same criteria and with equal accuracy in all groups. With his assistance we proceeded to analyze the data in detail from several angles as

TABLE 3—Relationship of Duration of Colds to Number of Attacks per Individual

Indls Having	Group A				Group B				Group C			
	No. Indls	Total Colds	Average Duration		No. Indls	Total Colds	Average Duration		No. Indls	Total Colds	Average Duration

described in an effort to discover whether this apparent difference in duration was consistent throughout or whether it was associated with some particular extenuating factor.

When the percentage incidence of colds of varying lengths in the three groups was studied (table 2), it was found that colds of intermediate length (from eleven to twenty days) occurred with about equal frequency in all groups and that the number of short colds (ten days or less) was greatest, and of long colds (twenty days or longer) least, in group A. This was more or less expected and merely supports the finding that colds in group A were of somewhat shorter average duration than in groups B and C. That this is equally

true in subjects having one cold or several during the period of observation is brought out in table 3, which is based on 631 colds occurring in 189 individuals. Here it will be noted that, irrespective of the number of attacks suffered by the individual, the average duration of the colds was always shorter in the group taking vitamin A.

When the factor of season was investigated, interesting and possibly pertinent information was obtained. For this analysis, colds were classified arbitrarily as winter colds when beginning in the periods (a) Feb. 4 to April 29, 1933, and (b) Nov. 12, 1933 to March 3, 1934; spring and summer colds, those arising in the period April 30 to August 19, and fall colds, those included in the period August 20 to November 11. The time periods designated were selected on the basis of the fairly well demarcated incidence peaks as shown in figure 2. Only the colds of those who completed the experiment and whose colds had ended have been included. Table 4 shows the results.

TABLE 4.—Relationship of Duration of Colds to Time of Year When They Occurred

Period of Year	Group A 58 Individuals		Group B 63 Individuals		Group C 68 Individuals	
	Number of Colds	Average Duration	Number of Colds	Average Duration	Number of Colds	Average Duration
1st winter period Feb. 4 Apr. 29	69	7.36 ± 0.41	102	9.23 ± 0.47	110	12.45 ± 0.82
Spring and summer colds Apr. 30 Aug. 19	26	10.04 ± 0.70	0.45	10.80 ± 0.93	0.40	11.50 ± 1.24
Fall colds Aug. 20 Nov. 11	54	11.04 ± 0.77	0.93	11.21 ± 0.77	0.92	11.88 ± 0.74
2d winter period Nov. 12 Mar. 3	60	9.58 ± 0.46	103	12.47 ± 0.73	105	12.90 ± 0.80
Totals and averages	199	9.38 ± 0.30	214	10.88 ± 0.36	208	12.14 ± 0.43

If the first group of winter colds is left out of consideration for the moment, certain definite facts appear: (a) Spring and summer colds and fall colds are of approximately the same duration in all groups. (b) Winter colds in the group receiving vitamin A are shorter by nearly three days than those in the two control groups. If it were not for the fact that the observations for the first winter period, particularly with respect to the viosterol control group, are not quite consistent with those in the second winter period, these data would lead logically to the conclusion that vitamin A, as given, shortens the duration of colds in winter but has little effect on summer colds. It is true that the colds in the group receiving vitamin A were distinctly shorter in the first winter period, but colds in the viosterol control group, though longer than these, are definitely shorter than those in the group receiving no vitamin. To be consistent, colds in the last two groups should have been of equal length, as they have been through all other periods. As suggested, during the first winter period our data on duration may have been somewhat less exact than later when we had thoroughly educated our subjects in the matter of accurate

⁹ Doull, J. A.; Herman, N. B., and Gafafer, W. M. *Am. J. Hyg.* 17: 536 (Mar.) 1933

reporting of termination. This may be an explanation of the discrepancy but should be accepted with caution, as errors in reporting should have been equalized by random selection. Nevertheless, in spite of this inconsistency the evidence that vitamin A shortens colds moderately in the winter months must be considered suggestive.

Infections Other than Colds.—In the period of observation, ninety-five infections of the upper respiratory tract other than colds occurred in the group. These included acute attacks of tonsillitis, pharyngitis, laryngitis, bronchitis and influenza, of which we had only two cases in the period of observation. They were not studied in detail. They are of interest mainly in the fact that their distribution in the three groups was approximately equal, being respectively thirty-four, thirty-two and twenty-nine, thus indicating that supplemental vitamin A has no influence on their incidence. These results are in harmony with the observations reported for children by Hess and his co-workers.³

SUMMARY AND COMMENT

With a view to ascertaining whether supplementary feeding with vitamin A would influence the incidence, severity or duration of colds, a group of young adult volunteers, numbering 241 at the beginning of the experiment and 211 at the end and divided into test and control groups by random selection, has been kept under observation for a period of fifty-six weeks beginning February 1933. Vitamin A in the form of halibut liver oil was administered in excess in large weekly doses to the test group. That this more convenient method of giving the vitamin weekly is as effective as when given daily was demonstrated experimentally by the successful protection of rats against characteristic vitamin A deficiency when the material was administered in adequate amounts at intervals of one, two and three weeks.

The results in regard to incidence indicate clearly that supplemental feeding of vitamin A in no way reduces the number of colds. The weekly attack rate as charted in figure 2 shows an incidence curve that is essentially the same in the vitamin A group as in the controls. The average incidence rate per person for the total period of fifty-six weeks was practically identical in the three groups, being 3.41 colds per person for the vitamin A group, 3.56 for the viosterol control group and 3.25 for the group receiving no vitamin at all. Respiratory infections other than colds also appeared with the same frequency in the three groups. Vitamin A failed to influence significantly the relative severity of colds. Although severity in colds is not a conspicuous finding, when judged by the standards adopted, 158, or 21 per cent, of the total colds observed fell into this class. Of these, almost exactly equal numbers fell into the test and control groups.

With respect to duration, the experimental data have been less easy of interpretation. Colds occurring in spring, summer and fall showed very little difference in length in the three groups. In winter infections, however, there was definite shortening, by two or three days, of the average duration of colds occurring in the group taking vitamin A. Certain inconsistencies in our results, as noted, have made us feel the necessity for caution in drawing positive conclusions. The evidence, however, is at least suggestive that vitamin A has a slight shortening effect on colds occurring in the winter. Whether this difference in winter as compared with

spring, summer and fall bears any relationship to the reduction of leafy vegetables in the diet in the winter months with consequent decrease of provitamin and whether, if confirmed, it represents a seasonal deficiency analogous to that associated with avitaminoses in general is a matter for speculation.

SUMMARY AND CONCLUSIONS

1. The effect of vitamin A on the incidence, severity, and duration of the common cold has been studied.
2. It has been shown that vitamin A in the form of halibut liver oil may be administered effectively in large single weekly doses.
3. Vitamin A has no effect on the incidence or severity of colds.
4. Suggestive but not conclusive evidence indicates that vitamin A shortens colds slightly in the winter months.

ABSTRACT OF DISCUSSION

DR. K. K. CHEN, Indianapolis: In presenting their almost negative results with vitamin A for the treatment of the common cold, Drs. Shibley and Spies have rendered a great service to the medical profession. For some years vitamin A was supposed to prevent infection, but evidence is accumulating to show that the claim is not justified. It was shown that vitamin A is useless in the treatment of pneumonia or tuberculosis, in the prophylaxis against respiratory infections among infants and school children, and in the reduction of incidence of otitis media in scarlet fever. Drs. Shibley and Spies have now concluded that vitamin A has no bearing on the number or severity of common colds. Whether or not it shortens the duration of colds in the winter months is a question requiring additional proof.

DR. TOM D. SPIES, Cleveland: Dr. Shibley and I found out that one can protect rats, even in their most susceptible period of life, against vitamin A deficiency by giving a large amount of the vitamin at varying weekly intervals. That may or may not be of clinical importance. We make no claim. We don't even advise pediatricians to try it. I do happen to know that some babies do not like cod liver oil, do not like other preparations, and therefore do not take ample quantities. At the present time there are new methods. The potencies have been so increased that one could struggle perhaps with a weekly or biweekly dose a little easier than with a daily dose. However, neither do we make this as a recommendation.

DR. WILLIAM J. KERR, San Francisco: The authors suggest that vitamin A has little value in protecting the nose from colds. The autumnal rise in the incidence of colds was not prevented by the use of vitamin A, which is abundantly available during the summer and fall months in the dietary. At the University of California we have not been able to transmit the common cold to susceptible persons, even though they are known to have many colds during the year, so long as we keep the environment constant and at a comfortable level. It has seemed to me that probably the defect or fault is a constitutional one and is connected with the autonomic nervous system. These individuals were unable to respond normally to the environment and fail to respond when the cooling power of the air is suddenly increased.

DR. RUSSELL L. HADEN, Cleveland: Dr. Shibley is very much interested in the reproduction of the common cold in the chimpanzee. I wonder whether he has tried the effect of vitamin A on the experimental production of the common cold in the chimpanzee.

DR. GERALD S. SHIBLEY, Cleveland: I must answer Dr. Haden's question in the negative. The main reason is that chimpanzees cost from \$350 to \$700 and that therefore one would have too few animals for results of statistical significance. We have, as a matter of fact, kept our animals up on all vitamins but they still catch colds just as human beings do. I am rather interested in Dr. Kerr's remark about the noninfectiousness of colds. I was associated for a number of

years with Dr. Dochez in attempts at the experimental transmission of colds. We were successful in a large proportion of cases, tried not only with chimpanzees but also with human beings. It is true that we did not have the air conditioning but we had thermostatic control. There is one question which I should like to ask which is rather interesting in the light of Dr. Kerr's statement that one has no chilling, under the conditions of his experiments, and therefore gets no colds. It is a fairly well known fact that explorers who have gone to the north pole for as long as two or three years, in spite of exposures to cold, to fatigue, and to practically every type of elemental exposure, never get colds. The minute they hit civilization, where colds are present, back come colds again.

A NEW BIOLOGIC TEST FOR HORMONES IN PREGNANCY URINE

PRELIMINARY REPORT

A. E. KANTER, M.D.

C. P. BAUER, M.D.

AND

A. H. KLAUANS, M.D.

CHICAGO

It has been known that male fish of certain species undergo color changes during the breeding season and develop what is known as the "wedding dress." These chromatophore reactions have been developed artificially by stimulation with various hormone preparations.¹ Following the same principle it was thought that analogous reactions might be obtained on female fish of species that have an externally visible oviduct. Tozawa² found that males of the Japanese bitterling (*Acherlognathus intermedium*) developed a chromatophore reaction to hormones injected only during the breeding season, April 15 to July 1. In 1932 Fleischmann and Kann³ reported that female bitterlings show an enlargement of the ovipositor following injection of an estrogenic preparation (Progynon) in doses of from 40 to 120 mouse units, while physiologic solution of sodium chloride and an anterior pituitary extract yielded no reaction. These authors claim a lengthening of the oviduct with estrogenic substance during the quiescent period. In 1933 Szusz⁴ tested female bitterlings with boiled and unboiled urine from pregnant women, male urine, estrogenic substance (Progynon and Hogival), and anterior pituitary extract (Glandu-antin), 10 cc. of each to 1 liter of water in which the fish are placed. During the breeding season forty-eight fish were tested and all showed lengthening of the ovipositor in from thirty-six to seventy-two hours with both the boiled and the unboiled urine. Six fishes tested with anterior pituitary extract showed no changes. Urine from twenty nonpregnant females gave twelve positive and eight negative reactions. Male urine caused some lengthening in seven of the thirty-seven tested, greater lengthening in twenty-two instances, and no reaction in eight. This author tested twenty-two fish

from July 1 to August 15 and all gave negative reactions. Szusz does not know what is responsible for the reaction. He concluded that full lengthening of the ovipositor takes place in seventy-two hours, that the test can be positive only during the breeding season, that male urine may cause a positive reaction, and that a negative reaction during the breeding season is absolutely indicative of the absence of pregnancy.

The senior author felt that the possibilities of the female bitterling test deserved further investigation. After sporadic attempts at testing on the various problems associated with this research, the results became so confusing that it was felt tests could not be conducted along scientific lines until the fish had been standardized; i. e., it was necessary to know in advance whether each fish was capable of responding positively to urine from a known pregnant woman and that the same fish would not react to the urine from a patient who was not pregnant. Although a great number of tests have been carried out, only those run subsequent to Aug. 1, 1934, at which time our supply of fish was standardized, are included in this report. In this process of standardization it was found that some fish did not respond to pregnancy urine because of immaturity or stunted size, while others of apparently mature size were refractory to the active principle for some unknown reason. Because of the number of fish that fell in this classification, it is imperative that this standardization process be carried out. After a positive test it requires from fourteen to twenty days for the ovipositor to return to its normal length, during which time the fish cannot be used for testing purposes.

TECHNIC

A previously standardized fish is put in a two quart bowl which contains one quart of water at the proper temperature, about 75 F. The fish is observed to make certain that the oviduct is not beyond normal limits. Four cc. of the urine to be tested is put into this water. The fish is observed at twenty-four hour intervals. If the test is found to be positive after the first twenty-four hours the test is discontinued; if negative, it must be carried out for seventy-two hours before a definitely negative report may be given, in spite of the fact that about 80 per cent of our positives were positive at the end of the first twenty-four hours. Normally the oviduct is about 2 mm. in length and reaches less than half the distance to the end of the ventral fin. With a positive reaction the ovipositor reaches past the edge of the ventral fin or to a length of 15 to 25 mm. After the test is completed the fish is put into a tank for recovery and left for from two to three weeks in order to allow for the regression following the positive reaction. It may then be used for other tests.

RESULTS

At the outset it was deemed advisable to run the fish tests parallel to Friedman tests in order to determine the relative merits of the two. The laboratories of the Presbyterian and Mount Sinai hospitals graciously cooperated with us in this work by giving us urines and reports on their Friedman tests. To date we have thirty-one such tests, with twenty-seven absolute checks and four discrepancies between the two tests. The four cases in which there were differences of result are as follows:

1. An ectopic pregnancy, ruptured, proved at operation. Fish test positive. Friedman test negative.

Read before the Chicago Gynecological Society, Nov. 16, 1934.

2. Woman, aged 51; three months amenorrhea with subsequent menstruation. Fish test positive. Friedman test negative.
3. Patient four days beyond expected date for menstruation. Sterile five years. Fish test negative. Friedman test positive. Pregnancy still unproved. Later fish test positive.
4. Patient four days past expected menstruation. Fish test negative. Aschheim-Zondek test (commercial laboratory) negative. Six days after expected menstruation, fish test negative, Friedman test positive. Twelve days after expected period, fish test negative. Histologic studies of curettage material revealed the presence of a very early pregnancy.

There have also been tests run on five ectopic pregnancies proved at operation, which have all been positive but which had not been checked against the Friedman test.

COMMENT

We believe that we have a test for some element which exists in excess in the urine of pregnant women, most probably estrogenic substance. From a study of the literature and its correlation with our observations such

Our results will probably be more consistent and better classified when we have developed our technic both for handling the fish and for the actual carrying out of the tests. This test will prove of clinical value with advantages over the Aschheim-Zondek and the Friedman test. The fish are primarily cheaper than rabbits or mice, are easier to maintain because of the small amount of space, food and care required in their handling, and at the end of the test it is not necessary to operate on the experimental animal and destroy it, as the fish may be used repeatedly for testing purposes. Another point in favor of this test is the fact that most positive results are obtained in twenty-four hours, while the other tests must run from forty-eight to seventy-two hours.

Should our predictions prove correct, the fields of research that may be opened by such a test are virtually boundless. To cite a few problems that we contemplate attacking as soon as our supply of test animals becomes sufficiently numerous: quantitative determinations for estrogenic substance at periods of physiologic and pathologic variation (menopause, puberty, various stages in the menstrual cycle, so-called functional amenorrheas, menorrhagias and metrorrhagias, and feminizing and defeminizing tumors); quantitative tests in hydatidiform mole and chorionepithelioma; tests for the presence of excess hormones associated with fibroid tumors and malignant conditions; methods of assay for the retention of potency and standardization of commercial hormone products; tests for the differential diagnosis of ectopic pregnancy. It is very important that we determine at an early date the time during pregnancy when the positive test first appears and the time during the puerperium when the test becomes negative.

310 South Michigan Avenue — 55 East Washington Street.

Japanese bitterling (*Acheroglyphus intermedius*). A, normal, or negative test; B, positive test.

a conclusion can be reached. First, the authors referred to all had uniformly positive results with the use of estrogenic hormones and fairly consistent negative results with anterior pituitary extracts. Boiling destroys the gonadotropic factor of pregnancy urine, yet boiled urine gave results identical to those obtained with unboiled urine. At certain times in the life of a woman there is a physiologic excess of the follicular hormone, particularly during the onset of the menopause, and we take the liberty of citing case 2 as being illustrative of this, explaining the negative Friedman test on the basis that that test is dependent on the presence of an excess of anterior pituitary-like gonadotropic hormone rather than estrogenic substance. Several tests that we have carried out with some commercial products have given positives with estrogenic preparations and negatives with gonad-stimulating products.

Clinical Notes, Suggestions and New Instruments

SUPERIOR LARYNGEAL NEURALGIA RELIEVED BY OPERATION

DEAN H. ECHOLS, M.D., AND JAMES H. MAXWELL, M.D.
ANN ARBOR, MICH.

True neuralgia of the superior laryngeal nerve is a distinct clinical entity comparable to trigeminal and glossopharyngeal neuralgia. It is characterized by paroxysms of unilateral, lancinating pain, which radiates from the side of the thyroid cartilage to the angle of the jaw and sometimes to the ear. There is a trigger zone at the plica of the nerve in the pyriform sinus. The pain is ordinarily initiated by swallowing but can be produced by touching the trigger zone with a probe. The other objective finding is a pressure point on the skin surface just above and lateral to the thyroid cartilage, where the sensory branch of the nerve pierces the hyothyroid membrane. Between the seizures, which may last from a few seconds to a minute, the patient is free from discomfort. As in other cranial nerve neuralgias, the attacks usually appear after middle age and increase in frequency and intensity. As a rule there is no disease of the pharynx or larynx present. Treatment directed at a coexisting tonsillitis or laryngitis is as futile as the extraction of teeth for the *douloureux*. Superior laryngeal neuralgia should not be confused with the more or less constant pain due to a malignant condition or tuberculosis of the larynx and epiglottitis. The laryngeal crises of tabes must also be ruled out. It is most important to differentiate it from glossopharyngeal neuralgia, in which syndrome the pain radiates to the ear from the tonsillar region, which is the trigger zone.

From the Departments of Neurology and Otolaryngology, University Hospital.

Although there are few case reports, especially in English, this condition is probably not uncommon. It was first described by Avellis¹ in 1900. Hutter² reported a series of cases, some of which were treated by alcohol injection. Bailey³ and Harris⁴ both consider this to be a clinical entity, and the latter reported a case cured by alcohol injection.

Before our case is presented, the anatomy of this nerve will be abridged as follows: It is a branch of the vagus, arises from the ganglion nodosum, descends by the side of the pharynx behind the internal carotid artery, and divides into the internal and external branches. The internal branch, which is the one concerned in our report, pierces the thyrohyoid membrane and is distributed to the mucous membrane of the epiglottis, the base of the tongue, and the larynx above the vocal folds. The external branch is largely motor, supplying mainly the cricothyroideus.

REPORT OF CASE

N. K., a mechanic, aged 51, was admitted in September 1933. Nine months previously he began to have lancinating, burning pains in the left side of the neck, which radiated from the thyroid cartilage toward the angle of the jaw. At first the attacks were infrequent and lasted only a few seconds, but they gradually increased in number and duration. He was often awakened at night. Later he became aware that swallowing produced the pain. Considerable weight had been lost.

Observation showed that the patient was having attacks of excruciating pain about every twenty minutes. During the seizures, which rarely lasted over ten seconds, he would press the hand on the neck and hold the breath. Between the paroxysms he was comfortable but apprehensive.

Examination showed mildly inflamed tonsils, and a smooth, pea-sized nodule on the left vocal cord. The cords functioned normally. The cranial nerves were negative except for a tendency of the tongue to protrude to the right. The uvula rose in the midline on phonation and the gag reflex was present. Probing the tonsillar region caused no pain. Sensation was normal over the entire tongue and palate. There were no sensory changes on the neck, but there was a point, just above and to the left of the thyroid cartilage, which was painful to pressure. Tendon reflexes were normal. The physical examination showed little more than moderate peripheral arteriosclerosis and an adenomatous goiter. The blood pressure was 110 systolic, 60 diastolic. The Kahn test was negative. Urinalysis showed a trace of sugar on two occasions. Roentgenograms showed normal lungs and an increase in thyroid tissue with deposits of calcium.

Several days after admission, the vocal cord nodule was excised but without relief. Microscopic examination showed chronically inflamed and dilated mucous gland ducts. On two occasions complete relief from pain was obtained for a ten hour period by the injection of 1 per cent procaine hydrochloride into the region of the internal branch of the superior laryngeal nerve. The nerve was located by probing with the needle until the neuralgic pain was reproduced.

Under local anesthesia the hyoid attachments of the omohyoid and thyrohyoid muscles were sectioned (by J. H. M.) through a left collar incision at the level of the hyoid bone. The internal branch of the superior laryngeal nerve was exposed and identified by inserting a needle, typical pain being produced. Absolute alcohol was injected and a 1.5 cm. section of nerve excised. Microscopically, it showed congestion.

When last heard from, seven months later, the patient was in good health and completely free from pain.

COMMENT

The similarity of laryngeal, trigeminal and glossopharyngeal neuralgia was strikingly demonstrated by this case. The essential difference lies in the location of the trigger zone and the distribution of the pain. Our patient suffered paroxysms of

lancinating pain in the side of the neck which were brought on by swallowing. Between attacks he was entirely comfortable. Stimulating the nerve reproduced the pain, procaine injection gave temporary relief, and section gave permanent relief (seven months, plus).

As neuralgia frequently returns after section or alcohol injection of a peripheral nerve, it is possible that our patient may have a recurrence. In that event, section of the vagus nerve just above the ganglion nodosum will be considered. Although neuralgia should be looked on as a symptom and not a disease, the cause in most cases is unknown. The mild tonsillitis and small vocal cord cyst in our patient were undoubtedly incidental occurrences of no significance.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT.

HOWARD A. CARTER, Secretary.

AIRCO OXYGEN THERAPY REGULATOR ACCEPTABLE

The Airco Oxygen Therapy Regulator, Style 8481 (Float-Gage Type), is manufactured by the Air Reduction Sales Company, Jersey City, N. J. The purpose of this instrument is to control and to meter the flow of oxygen to a tent, chamber, catheter or inhaler.

This regulator is known as a double reduction or two stage regulator; that is, there are two stages of pressure reduction. In the first stage the pressure is reduced from cylinder pressure, which may be as high as 2,000 pounds per square inch, down to approximately 65 pounds per square inch. In the second stage this 65 pound pressure is reduced to a pressure the exact value of which is determined by the degree of strain imparted to the adjusting spring by means of the adjusting screw. (This second-stage pressure in no case is greater than approximately 15 pounds per square inch for a full scale reading of the float gage.) It will be seen that the oxygen entering the regulator, after passing through the glass wool filter, is permitted to discharge from the high pressure nozzle under control of the high pressure seat. The high pressure seat is carried in the short end of a valve lever the exact position of which is determined

Airco Oxygen Therapy Regulator.

by the position of the high pressure diaphragm. If the pressure beneath this diaphragm tends to fall at any time, the first stage control spring forces the diaphragm inward and consequently rocks the lever in such a manner as to permit a freer discharge of oxygen from the high pressure nozzle, so that the pressure beneath the diaphragm is again restored to its normal level. The reverse takes place in case the pressure beneath the diaphragm tends to become excessive. The result is that a rate of discharge from the nozzle is maintained equal to the rate of discharge from the regulator.

The oxygen leaves the high pressure stage of the regulator by means of two diagonal vent holes in the guide thimble and then through the annular space afforded between the low pressure seat and the low pressure valve lip, the latter being machined directly into the regulator body. The discharge through this low pressure valve into the low pressure cavity is under control of the low pressure diaphragm and the adjusting spring. Any tendency for the pressure in the low pressure chamber to drop is compensated by an inward movement of the diaphragm, a greater separation of the low pressure seat from the valve lip and consequently a greater discharge of gas into the low pressure cavity. The reverse is true for any tendency for the delivery pressure to increase.

2. Hutter, F.: Ueber Neuralgien des Nervus laryngeus superior, Monatschr. f. Ohrenh. 63: 402 (April) 1929.

3. Bailey, Percival: Neuralgias of Cranial Nerves, S. Clin. North America 11: 61 (Feb.) 1931.

4. Harris, Wilfred: Neuritis and Neuralgia, London, Oxford University Press 1926.

The oxygen leaving the regulator passes directly into a flowmeter of the float-gage type in which the upward movement of the oxygen through a transparent, divergently tapered tube causes a stainless steel ball to rise to a level that is proportional to the rate of flow. The meter is graduated in liters per minute from 0.5 liter to 15 liters.

One unit was investigated in a clinic acceptable to the Council. The claims of the manufacturer were substantiated. The Airco Oxygen Therapy Regulator, therefore, is included in the Council's list of accepted devices.

Committee on Foods

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION, AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION.

RAYMOND HERTWIG, Secretary.

BORCHERDT'S DRI-MALT SOUP EXTRACT WITH ADDED POTASSIUM CARBONATE

Manufacturer.—Borchardt Malt Extract Company, Chicago.

Description.—Powdered, nondiastatic malt extract containing added potassium carbonate.

Manufacture.—Borchardt's Malt Soup Extract with added potassium carbonate (THE JOURNAL, Nov. 24, 1934, p. 1623) is further evaporated in "vacuum" at 71 C. to a powder and packed in cans.

Analysis (submitted by manufacturer).—	per cent
Moisture	3.8
Ash	2.9
Potassium carbonate.....	1.4
Fat (ether extract).....	0.0
Protein (N X 6.25).....	8.7
Reducing sugars as maltose.....	71.1
Dextrins (by difference).....	13.5

Calories.—3.7 per gram; 105 per ounce.

Claims of Manufacturer.—Used in the preparation of Keller's Malt Soup, also as a laxative modifier in the diet of obstinate cases of constipation in bottle fed babies.

VITAMIN D FORTIFIED PASTEURIZED MILK

Distributors.—

Amsterdam Dairy, Schenectady, N. Y.
Baker's Dairy, Boise, Idaho.
Blue Ribbon Creamery, Jackson, Miss.
The Guernsey Dairy Company, Owosso, Mich.
Lawrence Sanitary Milk & Ice Cream Co., Lawrence, Kan.
Peerless Dairy, Ltd., Windsor, Ontario, Canada.
M. H. Renken Dairy Co., Brooklyn.
Sanitary Dairy Company, Muskegon, Mich.
Sturtevant Ice Cream Company, Rock Island, Ill.
Superior Dairy Company, Davenport, Iowa.
Vitex Laboratories, Tacoma, Wash.
West Coast Dairy, Everett, Wash.
Williamsport Milk Products Co., Inc., Williamsport, Pa. (Hurr's)
Yakima Laboratories, Yakima, Wash.
York Sanitary Milk Company, York, Pa.

Description.—Bottled pasteurized milk fortified with vitamin D (vitamin D concentrate prepared from cod liver oil); contains 400 U. S. P. X (Revised, 1934) vitamin D units per quart.

Preparation.—The milk complies with legal requirements and is pasteurized by the standard holding method. See THE JOURNAL, July 1, 1933, page 34, for description of fortification with vitamin D.

Vitamins.—The vitamin D concentrate used and the fortified milk are regularly tested biologically. Clinical investigation shows this milk to be a reliable antirachitic agent, if the proper amount is used.

Claims of Distributors.—A vitamin D fortified, antirachitic pasteurized milk having otherwise the flavor and food values of usual pasteurized milk.

NOURON

Manufacturer.—Nouron Products Corporation, New York.

Description.—Dried granules of a dough composed of soy beans, whole durum wheat flour and dried egg yolk.

Manufacture.—Washed soy bean is softened with steam, mashed and mixed with formula proportions of whole wheat flour and egg yolk in a macaroni mixing machine. The dough is mechanically kneaded, forced by hydraulic pressure through dies containing small apertures, cut into small pieces by revolving knives, and dried on trays by air currents. The method of manufacture is essentially that for the preparation of macaroni.

Analysis (submitted by manufacturer).—	per cent
Moisture	5.8
Ash	2.4
Fat (ether extraction method).....	9.3
Protein (N X 6.25).....	26.2
Reducing sugars before inversion as dextrose.....	2.0
Reducing sugars after inversion as dextrose.....	7.0
Sucrose (copper reduction method).....	4.8
Crude fiber	3.1
Carbohydrates other than crude fiber (by difference)...	54.2
Lipoid phosphoric acid as P ₂ O ₅	0.049
Calcium (Ca)	0.10
Phosphorus (P)	0.16
Iron (Fe)	0.0016
Copper (Cu)	0.0012
Manganese (Mn)	0.01

Calories.—3.9 per gram; 111 per ounce.

KRIM-KO CHOCOLATE FLAVORED DRINK

Bottlers and Distributors.—

Better Dairy, Barnesville, Ohio.
Burnett Brothers Dairy, Bradenton, Fla.
Excelsior Sanitary Dairy, Frederick, Md.
Lorain Creamery, Lorain, Ohio.
George E. Lucas Dairy, Massillon, Ohio.
Med-O-Bloom Dairy, Kokomo, Ind.
Miami Home Milk Producers Assn., Miami, Fla.
Oatman Brothers, Inc., Aurora, Ill.
Peters Dairy, Michigan City, Ind.
The Producers Milk Co., Cleveland.
Riggle Dairy, Newcomerstown, Ohio.
St. Paul Milk Company, St. Paul.
Sunbury Milk Products Co., Sunbury, Pa.
Sunshine Farms, Inc., Lafayette, Ind.
Superior Dairy, Canton, Ohio.
The Sycamore Dairy, Haines City, Fla.
Victory Creamery, Emporia, Kan.
Virginia Dairy Company, Richmond, Va.
Warren County Dairy Assn., Warren, Pa.
Wendt's Dairy, LaSalle, N. Y.
Williamsville Dairy, Williamsville, N. Y.
Willowcreek Dairy, St. Clairsville, Ohio.
Winona Milk Company, Winona, Minn.
Woodlawn Farms Dairy, Kirkwood, Mo.

Licensor.—Krim-Ko Company, Chicago, manufactures the Krim-Ko Chocolate Flavored Drink Base and licenses its use, the name Krim-Ko, and standard advertising under definite contract conditions.

Description.—Pasteurized chocolate flavored sweetened skim milk; contains skim milk (from 0.5 to 1.5 per cent milk fat), sucrose, chocolate and cocoa, tapioca flour, salt and traces of tartaric acid and agar; flavored with imitation vanilla extract. See Krim-Ko Chocolate Flavored Drink, THE JOURNAL, June 30, 1934, page 2187.

SATURDAY, DECEMBER 29, 1934

THE MOTION OF GROWTH

Just what growth is, why it happens, how it can be influenced and why it is frequently abnormal are questions of great importance. This is especially true in relation to the great advances that have been made in our knowledge of nutrition. Heretofore most of the studies of growth have dealt mainly with the determination of changes in weight and height, the statistical analysis of these values and the correlation between them.

In a recent series of publications with the general title "On the Motion of Growth," Norman C. Wetzel has indicated clearly that there is little to be learned from more studies of growth that are limited in their scope to the measurement of absolute changes in weight and height alone. This investigator regards growth as a mode of motion and treats it by the methods of energetics and classic dynamics. This fundamental and original method of attacking the problem has necessitated critical redefinition of the phenomena of growth and metabolism.¹ Wetzel concludes that growth is determined by at least four distinct quantities, which he has termed the "resistance," "inductance," "permittance" and "net external work."² By the interplay of these four quantities the rate of growth is determined, and the latter is affected by alteration of any one or of more than one of these factors. The dependence of the rate of growth on these four quantities Wetzel has shown in a general mathematical expression.^{2a}

The most remarkable single contribution in this series of studies appears to be the finding of a direct dynamic relation between basal metabolism and growth.³ This is of great interest in the case of human beings, especially infants and children.⁴ Wetzel has developed the

first mathematical expression from which can be constructed ideal curves of both cumulative gain in weight⁵ and basal heat production^{3a} in man, from the early fetal to the adult stage. These studies make it possible to comprehend the difference between the metabolism of youth and of old age, whether in bacteria,^{3b} plants, tissues in vitro, amphibians,^{3c} birds, lower mammals, or man.⁶ In all these, according to this author, his fundamental equation is satisfied.^{2a}

Of significance is the establishment for the first time⁷ of a critical period in the life of a human being at birth, at which time there is a maximum rate of gain. Of still greater practical significance is the finding of a minimum rate of gain,⁵ rate of growth⁶ and basal heat production^{3a} at the end of the period of infancy, at which time there is "comparative rest in the motion of growth." These three curves remain at an unusually low level for several years following the end of infancy, offering an explanation for the well known poor appetite and failure to gain of children in this age period.

In these studies,⁸ starvation (in which the rate of growth is negative) and its effect on heat production have received the consideration they deserve. Wetzel has been led to conclude⁶ that excessive rate of gain during infancy and childhood is accompanied by an even greater rate of wasteful heat production. This may be a matter of serious concern in the case of the premature infant, for whom an excessive rate of gain may have grave consequences. By establishing a relationship between heat production and growth, Wetzel has thrown new light on data already available^{3c} and has given a new stimulus to the study of the fundamentals underlying the phenomenon of growth in general.

PUERPERAL GYNECOLOGY

In the development of obstetrics, few contributions have been so worthy of note as to constitute landmarks. Invention of the obstetric forceps, recognition of the cause of puerperal infection, the use of anesthesia, the development of the various technics of delivery, and recently the fundamental studies in endocrinology with their one important practical result, the pregnancy test, might be mentioned as of great significance. The uncertainties and hazards of childbirth have been materially reduced; the end results, however, as has been pointed out repeatedly, are still not all that they might be. The newer contributions to obstetrics are unfortunately not universally applied; the incidences of morbidity and of mortality remain all too high. Apart from these, what may be termed remote morbidity, and even mortality

not immediately credited to childbirth, are factors in the health of the community that receive little attention. The poor health of the woman with relaxed perineal and pelvic structures for varying periods of years following delivery or the plight of the woman with lacerations and erosions of the uterine cervix, which later becomes the seat not only of infection but ultimately of malignant change, may often reasonably be charged against obstetrics. Thus it is recognized that the concern of the obstetrician really does not cease with delivery of the baby and survival of the mother; the subsequent health of the mother should in considerable degree be his responsibility also.

In the trend of the clinician to specialize, obstetrics and gynecology have branched apart. Perhaps this schism has become too great. Bubis¹ has pointed out the tremendous advantage to the parturient entailed in the immediate, or almost immediate, repair of the genital tract. Relaxation of the birth canal and laceration of the cervix are said to occur in at least 75 per cent of women who have borne one or more children. Often this may consist only of a small tear in the cervix, a slight displacement of the uterus, a tendency to cystocele or urethrocele, or a small laceration or slight relaxation of the perineum. But, as Bubis has emphasized, no such lesion is small enough to neglect, as nature rarely cures even these satisfactorily. Thus he has reported² 1,353 cases in which immediate or semi-immediate gynoplastic repair was done with a low morbidity rate and an unusually low mortality rate. The subsequent health of the parturients, relative to gynecologic complaints, was unusually good. In addition, a tremendous economic and sociological advantage accrued to these patients. Many of them, had they not had immediate surgical treatment, would have had to return to the hospital at some subsequent time for this attention; others would have gone through life with the ill health attendant on the damage resultant from parturition, in many cases with superimposed pathologic changes, which similarly often fail to be treated. The advantage to the patient of a single rather than of two or more sojourns in the hospital must be obvious. Bubis has estimated that the resultant economic saving to the community in his series of 1,353 cases alone, in the obstetric service of but a single hospital, amounted to more than \$450,000. This must be a small item, however, compared to the benefit to the health of these women, who in many cases were spared years of semi-invalidism. Only a comparatively small proportion of

patients find it expedient to return to the hospital for subsequent treatment; others go through years of needless physical disability.

These procedures, while advocated by many obstetricians, have been criticized by other obstetricians and by gynecologists on various grounds. The contusion of the tissues incident on parturition, it is said, makes the extent of the injury difficult to evaluate and renders the parts unsuitable for extensive repair. Hemorrhage is said to be more severe and the incidence of infection higher than normal. Other objections also have been raised. But the fact that in recent years a considerable number of obstetricians have adopted, with notable success, immediate or semi-immediate gynoplastic repair as a standard procedure indicates that in experienced hands (in those cases in which certain pathologic conditions and infections do not render it unsafe) the hazard of this type of surgery is not prohibitive and the advantages are considerable.³

AMINO ACID—GLYCINE—THERAPY IN THE MYOPATHIES

Recent investigations of the influence of amino acid therapy on the unbalanced creatine-creatinine metabolism associated with certain types of myopathies have yielded interesting results. These appear to be of particular significance when the alterations in creatinuria are related to the favorable prognosis in this clinical syndrome. Gibson and Martin¹ and Brand, Harris, Sandberg and Ringer² were among the first to recognize the importance of glycine³ in their investigations of the origin of creatine. The latter workers showed that the ingestion of this amino acid or of gelatin, which is high in glycine, by patients with progressive muscular dystrophy was followed by a large increase in the creatinuria. This significant relationship between glycine, a substance that the normal person can readily synthesize, and creatine, which has been demonstrated to play an important part in muscle function, suggested to several investigators that the prolonged administration of the amino acid might have an influence on the clinical and metabolic course of muscular dystrophy. Striking confirmation of this hypothesis was reported from the laboratory of Karl Thomas in Leipzig.⁴ Six cases were studied during eight experimental periods each of a few months' duration. The daily ingestion of from 15 to 20 Gm. of glycine increased the daily excretion of creatine to a value that was from 100 to 1,000

per cent higher than the previous creatinuria level. After a period of some weeks the creatinuria began to decrease despite the continued administration of glycine, falling finally to the former control level. Coincident with this diminished creatinuria there was an increased excretion of creatinine and an improvement in the patients' ability to retain ingested creatine. These interesting alterations in the metabolism were accompanied by remarkable improvement in the condition of the patients. Muscles that previously had felt tired now seemed refreshed and the patients often expressed the desire to make muscular movements that had not been possible for a considerable period. Interruption of the glycine treatment resulted in a gradual disappearance of the improvement, and the disease eventually returned to its previous status. Resumption of the glycine administration again resulted in the previously described improvement.

These important results have stimulated many clinicians to use glycine, with and without ephedrine, in the treatment of various types of myopathies. However, conflicting opinions have arisen regarding the various metabolic relationships and therapeutic effects following either glycine or glutamic acid therapy, the latter amino acid having also been found to be efficacious by some workers. This disagreement is probably due to a considerable extent to the failure to distinguish accurately the various types and stages of muscular dystrophy and to evaluate correctly those muscular atrophies which are secondary to pathologic lesions in the central nervous system. A good summary of this literature, together with an account of metabolic studies on thirty-four patients, representing eleven distinct types of myopathies and atrophies, has been recently presented by investigators of the Louisiana State University Medical Center.⁴ Either glycine or glutamic acid therapy was demonstrated to be capable of augmenting the creatinuria present in each of ten different types of cases. Concomitant with this increased excretion of creatine, an objective and subjective improvement was present, the magnitude of which was dependent on the nature of the myopathy. In general, the cases classified as primary myopathies and myasthenia gravis showed distinct clinical improvement, except in a few cases of the former type in which the disease had advanced to the stage of complete muscle degeneration. However, while some of the muscular dystrophies were greatly benefited, no objective improvement was observed in the neuromuscular atrophies, despite the fact that the creatinuria present was influenced by the amino acid therapy. In a few instances of the latter disease there was subjective improvement or merely an arrest of symptoms.

These investigations serve to emphasize anew the importance of the amino acid treatment in certain of

the myopathies, to add metabolic evidence of the differences existing among these various muscle diseases, and to elucidate the function and importance of creatine and creatine precursors in muscle physiology.

Current Comment

FEDERAL FOOD AND DRUGS ACT APPROPRIATIONS

For the enforcement of the federal Food and Drugs Act during the current fiscal year, which ends June 30, 1935, Congress appropriated \$1,161,477. Thus, Congress authorized the expenditure of less than one cent each for every man, woman and child in the United States to protect them during an entire year from the dangers of adulterated and misbranded food and drugs. The appropriation for the current year, too, shows a decrease as compared with the appropriation for the fiscal year ended June 30, 1934, which in turn was less than the appropriation for the preceding fiscal year. This apparent tendency to appropriate less and less money for the enforcement of the federal Food and Drugs Act seems hardly consistent with the increasing federal expenditures in other fields. Irrespective of the outcome of proposals to revise the federal Food and Drugs Act now in force, so as to increase its protective value, the Seventy-Fourth Congress, which convenes January 3, should not hesitate to make available funds sufficient to afford the utmost protection to consumers that is possible under the existing law. The officials of the Food and Drugs Administration will, it may be assumed, give to Congress facts on which it may form an intelligent judgment when it considers the appropriation for carrying on such activities. Elsewhere in this issue appears a résumé of the activities during November. These are but a slight indication of the good that this department, with sufficient support, might accomplish for the health of our people. There is much talk of new legislation. Why not make even more effective the provisions we now have for this service?

Association News

MEDICAL BROADCASTS Columbia Broadcasting System

The American Medical Association broadcasts on a Western network of the Columbia Broadcasting System each Thursday afternoon on the Educational Forum from 4:30 to 4:45, central standard time. The next three broadcasts will be delivered by Dr. W. W. Bauer. The titles will be as follows:

- January 3. Housing and Health.
- January 10. Diphtheria Must Go.
- January 17. The Good Old Days.

National Broadcasting Company

The American Medical Association broadcasts under the title "Your Health" on a Blue network of the National Broadcasting Company each Tuesday afternoon from 4 to 4:15, central standard time. The two broadcasts will be as follows:

- January 1. Holiday. No broadcast.
- January 8. Research in Surgery, Thomas S. Cullen, M.D.*
- January 15. Causes of Death in 1933, W. W. Bauer, M.D.

* Dr. Cullen will speak from the National Broadcasting Company's Studios in Washington, D. C., by special arrangement.

4. Tripoli, C. J.; McCord, W. M., and Beard, H. H.: Muscular Dystrophy, Muscular Atrophy, Myasthenia Gravis and Strabismus, J. A. M. A. 103: 1595 (Nov. 24) 1934.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

ARKANSAS

Personal.—Dr. Cad A. Henry, Clarendon, has been appointed director of the Saline County Health Department, succeeding Dr. T. C. Watson, who plans to engage in private practice.

Society News.—The Benton County Medical Society was entertained at dinner at Siloam Springs, November 8, by Dr. and Mrs. Lester L. Scott. Speakers were Drs. Lewis M. Henry, Fort Smith, on "Differential Diagnosis of Common Ear Conditions," and Frederick H. Krock, Fort Smith, "Carcinoma of the Cervix."—Dr. Jacques Forestier, Aix-les-Bains, France, discussed the treatment of arthritis before the Pulaski County Medical Society in Little Rock, November 30.

District Meetings.—Dr. William T. Pride, head of the department of obstetrics, University of Tennessee College of Medicine, Memphis, was the principal speaker before the Eighth Councilor District Medical Society at its meeting in Little Rock, December 5. Clinics formed the larger part of the scientific program. The eighth district encompasses the counties of Pulaski, Faulkner, Perry, Pope, Conway and Johnson.—Speakers before the Ninth Councilor District Medical Society in Harrison, December 4, included, among others, Drs. Herbert Fay H. Jones, Little Rock, on urologic backache, and Solomon F. Hoge, Little Rock, early syphilis.

CALIFORNIA

Society News.—A symposium on obstetrics was presented before the Alameda County Medical Association, December 17, by Drs. Theodore W. Weller, John W. Sherrick and Clarence A. DePuy, Oakland, and Clarence W. Page, Berkeley.—The Sonoma County Medical Society was addressed, November 8, by Dr. Thomas E. P. Gocher, San Francisco, on "Treatment of the Sympathetic Nervous System and Its Effect on Post-operative and Post-Traumatic Industrial Injuries."—At a meeting of the San Joaquin County Medical Society in Stockton, November 1, Dr. Carl L. Hoag, San Francisco, among others, discussed "Common Surgical Problems, with Special Reference to Appendicitis."—At a meeting of the San Bernardino County Medical Society, December 4, Drs. Donald H. Brumbaugh, Redlands, discussed "Hemorrhoids and Myles' Hemorrhoidectomy," and Norman J. Kilbourne, Los Angeles, "Local Anesthetics Producing Prolonged Anesthesia for the Elimination of Pain After Rectal Operations."—Dr. James W. Sherrill addressed the San Diego County Medical Society, December 11, on "Present Status of Diabetes Mellitus."—Attorney Joseph N. Sweet, San Francisco, addressed the Solano County Medical and Bar associations in Vallejo, November 13, on "The Problems and Opportunities of Our Professions."—The Los Angeles Society of Neurology and Psychiatry was addressed, November 21, by Drs. Charles LeRoy Lowman on "Orthopedic Reconstruction in Neurologic Cases" and Leo J. Adelstein, "Surgical Treatment of Brain Abscess."

CONNECTICUT

Fellowships for Study of Adolescence.—THE JOURNAL published a news item, December 8, announcing the establishment of five fellowships by the Rockefeller Foundation at Yale University School of Medicine for the study of adolescence. It was stated that "appointments are to be for two years and they are to expire in alternate years so that one of the two men will always have had one year's experience on the project." This quoted statement does not pertain to these scholarships but to a different project recommended by Dean Milton C. Winternitz in his annual report, the appointment of assistants to aid senior staff members in research.

ILLINOIS

Society News.—Dr. James R. Nakada, St. Louis, addressed the Belleville meeting of the St. Clair County Medical Society, December 5, on tularemia.—Dr. Irving H. Neece, Decatur, among others, addressed the La Salle County Medical Society in Streator, November 22, on "Importance of Hematuria in Diagnosis."—Dr. David J. Davis, Chicago, addressed the Kankakee County Medical Society, December 13, on "Relationship of the State University School of Medicine to the Medical Profession."

Chicago

Memorial to Dr. Billings.—A bronze tablet has been placed in the Country Home for Convalescent Crippled Children as a memorial to Dr. Frank Billings and bearing the inscription: "In Memory of Dr. Frank Billings 1854-1932, the great physician whose wise counsel and unfailing encouragement were an enduring benefaction to this home." The tablet is the gift of the home.

Medical Faculty Entertains Biologic Group.—The University of Illinois College of Medicine presented a program, December 7, when the biologic faculty from the university at Urbana visited the school. Speakers included the following:

Richard L. Webb, Ph.D., Mesenteric Lymphatics.
Dr. Lars F. Gulbrandsen, Passage of Bacteria Through Intestinal Wall.
Dr. William F. Petersen, Biologic Reflections of Meteorological Variability.
Dr. Eric Odberg, The Contribution of Neural Surgery to Medicine.
Dr. Ernst Gellhorn, The Influence of the Oxygen and Carbon Dioxide Tensions of the Inspired Air on Sensory Processes.
Dr. Robert W. Keeton, Studies in Obesity.

Society News.—At a meeting of the Chicago Tuberculosis Society, December 13, Drs. Elven J. Berkheiser spoke on "Bone and Joint Tuberculosis"; Meyer R. Lichtenstein, "Immunity in Tuberculosis," and Leo L. J. Hardt, "Gastro-Intestinal Tuberculosis."—Speakers before the Chicago Surgical Society, December 14, included Drs. Alexander B. Ragins, who presented a clinical report of "Strangulated Hernia Simulating Appendicitis."—The Chicago Ophthalmological Society was addressed, December 17, among others, by Drs. Carl O. Schneider on "Use of Prosthesis Over Unightly Eyes" and Harry S. Gradle, "Prevention of Blindness."—Speakers before the Chicago Society of Allergy, December 17, were Drs. Meyer R. Lichtenstein on "The Patch Test for Gold Hypersensitivity" and Ben Z. Rappaport, "Cartridge Method for Intracutaneous Tests."—Dr. Frederic J. Cotton, Boston, conducted an operative clinic at Cook County Hospital, December 20.

Personal.—Dr. David J. Davis has been made president of the Institute of Medicine of Chicago, succeeding Dr. Joseph L. Miller.—Mr. John B. Zingrone, roentgenologist of Mercy Hospital for twenty-two years, was awarded the Cross of Chevalier of the Order of the Crown of Italy at a banquet in his honor, December 6. Speakers included Mayor Edward J. Kelly, Dr. Philip H. Kreuscher, past president of the state medical society, and Dr. Julius H. Hess, president elect of the Chicago Medical Society.—Dr. John E. Gorrell, for the past two and one-half years assistant to the superintendent of the University of Chicago Clinics, resigned recently to become superintendent of the Falk Clinic at the University of Pittsburgh.—Miss Evelyn Wood, secretary, Central Council for Nursing Education and for the last five years president of the Illinois League of Nursing Education, died, November 27, of pulmonary embolism. Miss Wood was also secretary of the American Conference on Hospital Service.—Dr. Francis A. Dulak has been appointed a member of the Chicago Board of Health, succeeding Dr. Edward F. Dombrowski.

INDIANA

Society News.—The Seventh District Medical Society held a meeting in Martinsville, December 13; the program was devoted to symposiums on headache, dyspepsia, backache and chest pain.—A symposium on contagious diseases was presented before the Indianapolis Medical Society, December 18; speakers were Drs. Howard B. Mettel, Matthew Winters and Byron K. Rust. Dr. Howard Fox, New York, conducted a clinic on diseases of the skin before the society, December 11, and gave an address on common diseases of the skin.—Speakers before the Henry County Medical Society in New-castle, November 22, were Drs. Charles R. Bird and Albert Murray De Armond, Indianapolis, and Clyde C. Bitler, New-castle; their subjects were elementary diagnosis in everyday fracture, syphilis of the central nervous system, and Vincent's infection of the lung.—At a meeting of the Noble County Medical Society in Ligonier, December 4, Dr. Lyman T. Rawles, Fort Wayne, discussed sickness insurance and state medicine.—Dr. Oliver O. Alexander, Terre Haute, addressed the Sullivan County Medical Society in Sullivan, December 5, on cholecystitis and cholecystectomy.—A symposium on peptic ulcer constituted the program of the Clinton County Medical Society in Frankfort, December 6; speakers were Drs. Furman L. Pyke, Floyd A. Loop, Ray G. Ikons and Floyd T. Romberger, all of Lafayette.—The Jay County Medical Society, Portland, heard Dr. Grover C. Penberthy, Detroit, discuss the surgical treatment of children and the treatment of burns, December 7.

KENTUCKY

Society News.—Dr. William H. Park, New York, addressed the Jefferson County Medical Society, Louisville, December 3, on "BCG Vaccine and Its Control of Pulmonary Tuberculosis."—At a meeting of the Muldraugh Hill Medical Society, Elizabethtown, December 13, speakers were Drs. Charles L. Sherman, Millwood, on "Asepsis in the Home"; Robert Sory, Richmond, trachoma; Carl C. Howard, Glasgow, spinal anesthesia; William T. McConnell, Louisville, low forceps delivery, and Reason T. Layman, Elizabethtown, physical therapeutics.—Speakers before the Third District Medical Society in Bowling Green in October included Drs. Milton S. Lewis, Nashville, on "Treatment of Eclampsia"; Owsley Grant, Louisville, "Extrarenal Symptoms of Renal Disease"; Virgil E. Simpson, Louisville, "Use of Serums and Vaccines," and Paul York, Glasgow, "Hematuria."—Dr. Jacob Leland Tanner, Albany, addressed the Henderson County Medical Society, November 12, on "Treatment of Asthma."—Dr. Louis J. Karnosh, Cleveland, addressed the Campbell-Kenton County Medical Society, November 1, on "Difficulties in Cerebral Localization."

LOUISIANA

Society News.—Speakers before the Orleans Parish Medical Society in a symposium on cancer, December 10, were Drs. Edwin H. Lawson, Martin T. Van Studdiford and Ambrose H. Storck. The society was addressed, October 22, by Drs. Charles A. Bahn on "Recent Advances in the Treatment of Squint and Heterophoria" and by Hans E. A. Schroeder on "Glaucoma, a Nutritional Edema."

Personal.—Dr. Jackson J. Ayo, Raceland, has been named superintendent of the East Louisiana State Hospital at Jackson, succeeding the late Dr. John A. Thames.—Dr. Clarence Pierson, Pineville, was recently named special consultant to the three state eleemosynary institutions for the insane and feeble-minded: Central Louisiana State Hospital, Pineville; East Louisiana State Hospital, Jackson, and State Colony and Training School, Alexandria. Thirty years of Dr. Pierson's life has been spent as superintendent of the Central and East Louisiana state institutions.

Uniform Narcotic Act Adopted.—At the November session of the legislature, the state narcotic law was repealed and supplanted with the uniform narcotic drug law, effective December 6. The new law makes the same requirements for prescribing, dispensing, administering, handling and dealing in narcotic drugs in the state as are in force under the federal law and regulations, with one exception: that cannabis and its derivatives, including marihuana, are included under the state law as narcotic drugs. The use of the state narcotic order forms is discontinued, the only form necessary being the federal narcotic order form. Filling and filing of prescriptions and keeping of records must comply with the federal regulations. Twelve states have enacted the new uniform narcotic drug act.

MARYLAND

Memorial to Dr. Keating.—A bronze plaque was recently dedicated at the Rosewood State Training School, Owings Mills, in commemoration of the late Dr. Frank W. Keating, superintendent for thirty-eight years. Dr. Keating died February 18.

Society News.—Speakers before the Maryland Academy of Medicine and Surgery, November 20, in Baltimore, were Drs. George E. Bennett and Dean Lewis on "Diagnosis and Treatment of Lumbosacral and Sacro-Iliac Lesions" and "Tumors of the Breast," respectively.

Personal.—Dr. John M. T. Finney, professor emeritus of surgery, Johns Hopkins University School of Medicine, Baltimore, has been appointed a consultant to the Baltimore City Health Department.—Dr. William E. Martin, Randallstown, has been appointed health officer for the second district of Baltimore County, succeeding the late Dr. Harry F. Shipley.—Dr. Allan R. Dafoe, Callander, Ont., Canada, was the guest of Dr. Howard A. Kelly, Baltimore, recently.

MASSACHUSETTS

Personal.—Dr. George R. Minot, Boston, winner of the 1934 Nobel Prize in medicine, addressed the Royal Society of Medicine, London, November 29, on anemia.—Dr. Richard P. Strong, professor of tropical medicine, Harvard Medical School, Boston, has been named a member of the board of trustees of the Carnegie Institution.

Graduate Course.—The second annual graduate medical extension course of the Massachusetts Medical Society opened

December 11 and concluded December 19. Sessions were conducted in various places throughout the state and the subjects considered were cardiovascular disease, nutrition in health and disease, endocrinology, obstetrics and gynecology, surgery and industrial medicine.

Roentgenograms of Freshman Class.—Roentgenograms of the chests of all members of the freshman class at Massachusetts State College, Amherst, were taken early in December to discover incipient respiratory diseases. This is the first time that an entire class has received the test, which, in the future, will be a part of the regular physical examination. The project, which is carried on in cooperation with the state department of health, is an extension of similar work in the secondary schools.

Society News.—It was voted to reestablish a cancer clinic in Franklin County at the meeting of the Franklin District Medical Society in Greenfield, November 13. Dr. Roderick Heffron, Boston, addressed the meeting on "Lobar Pneumonia and Its Serum Treatment."—Dr. Gerardo M. Balboni, Boston, discussed "The Development in the Treatment of Pulmonary Tuberculosis from 1696 to the Present Time."—At a meeting of the Greater Boston Medical Society, December 4, Dr. William Jason Mixter, Boston, discussed "Common Medical Symptoms in Neurologic Surgery."—The Boston Society of Anesthetists was addressed, December 4, by Dr. Stanley J. G. Nowak on "The Carotid Sinus and Its Relation to Various Anesthetics."

Free Medical Lectures at Harvard.—January 6 will mark the opening of a weekly course of free medical lectures by Harvard University Medical School, to continue until March 24. The following speakers will participate:

Dr. Roy G. Hoskins, Gland Factors in Personality.
Dr. Howard B. Sprague, What Causes Heart Disease?
Dr. Alice Hamilton, Dangerous Trades.
James O. Pinkston, Ph.D., The Body Temperature.
Dr. Henry D. Chadwick, Tuberculosis as a Children's Disease.
Harry C. Trimble, Ph.D., Minerals in Our Bodies and Our Foods.
Dr. Howard F. Root, Diabetes.
David B. Dill, Ph.D., External Influences on Physical Activity.
Dr. Elliott C. Culler, Cancer.
George H. Parker, Sc.D., Twins and Social Biology.
Clarence B. Vaughan, D.D.S., Facts Regarding the Control of Diseases of the Gums.
Dr. Frederick C. Irving, Inheritance.

MICHIGAN

Cancer Survey.—Dr. Frank L. Rector, field representative of the American Society for the Control of Cancer, has been authorized to make a cancer survey of Michigan. The date to begin the survey has not been decided.

Personal.—Dr. Thomas H. Johnston, West Branch, director of the Children's Fund health unit number 2, comprising the counties of Alcona, Iosco, Oscoda and Ogemaw, has resigned on account of ill health after four years' service. He has been succeeded by Dr. Gladys J. Kleinschmidt, Ann Arbor.

Hospital News.—A new roentgenotherapy department was dedicated in Hackley Hospital, Muskegon, November 18, with Dr. James T. Case, professor of radiology, Northwestern University School of Medicine, Chicago, as the principal speaker. Dr. Leland E. Holly is head of the new department. The ceremony marked the thirtieth anniversary of the formal opening of the institution.

Meeting of School Physicians.—Four resolutions were adopted at a meeting of the Michigan Association of School Physicians in Lansing, November 8, which urged the enactment of suitable legislation requiring the examination of teachers, students and school health workers. The inclusion of the tuberculin test and roentgenograms in these examinations is a notable feature. Dr. John Sundwall, Ann Arbor, was elected president of the association; Dr. Clarence D. Barrett, Lansing, vice president, and Dr. Vladimir K. Volk, Pontiac, secretary.

MINNESOTA

State Society to Attend Science Meeting.—The eighty-second annual meeting of the Minnesota State Medical Association has been arranged to take advantage of the annual session of the American Association for the Advancement of Science at the Minneapolis Auditorium, June 24-26. There will be two joint sessions of the organizations, Tuesday morning and evening, June 25, at the University of Minnesota. Regular sessions of the science association will be confined to mornings so that members may attend the medical meetings in the auditorium in the afternoons.

Society News.—At a meeting of the Lyon-Lincoln Counties Medical Society in Tracy, November 11, the speakers were Dr. Francis J. Savage, St. Paul, president, and Mr. George Larson, field representative, of the Minnesota State Medical

Association.—The Red River Valley Medical Society was recently addressed at Thief River Falls by Drs. William G. Paradis, Crookston, on the comparative value of tuberculin tests; Edward Bratrud, urography with special reference to diagnosis, and Vernon L. Evans, Thief River Falls, tumors of the suprarenal.—At a meeting of the Renville County Medical Society at Bird Island, November 6, Mr. George Larson, St. Paul, discussed federal relief and compensation; Dr. John S. Holbrook, Mankato, perforated duodenal ulcers, and Dr. Max H. Hoffman, St. Paul, pneumonia.—Dr. Roy E. Swanson, Minneapolis, addressed the Rice County Medical Society, Northfield, November 27, on leukorrhea.—The Southwestern Minnesota Medical Society was addressed in Fulda, November 5, among others, by Drs. Harry W. Christianson and Lucius Haynes Fowler, Minneapolis, on proctology and appendicitis.—Dr. Harold S. Diehl, Minneapolis, addressed the Monroe County Medical Society in Rochester, October 16, on "The Common Cold."—Dr. Orwood J. Campbell, Minneapolis, discussed appendicitis before the Washington County Medical Society, November 13.

MISSOURI

Dr. Overholser Honored.—The Cass County Medical Society paid tribute to Dr. Milton P. Overholser, Harrisonville, at a recent meeting, in honor of his completion of fifty years in the practice of medicine. A charter member of the county society, Dr. Overholser has served as a member of the state board of health, of the pension board of examiners and as president of the Missouri State Medical Association.

Society News.—Drs. Leonard T. Furlow and Ernest Sachs discussed "The Care of Acute Brain Injuries" before the St. Louis Medical Society, November 30; Dr. Samuel B. Grant showed moving pictures on pernicious anemia. The Coronado Hotel has set aside a room to be known as the "St. Louis Medical Society Room," where members of the society may gather after regular meetings for "social relaxation." A symposium on vascular diseases of the extremities was presented before the society, November 20, by Drs. William H. Olmsted, Isaac Y. Olch and Paul S. Lowenstein.

Reestablishment of R. O. T. C. Urged.—At a meeting of the St. Louis Medical Society, December 4, a resolution was adopted urging the reestablishment of the medical reserve officers' training corps units as soon as possible. The resolution points out that the federal economies, which necessitated the discontinuance of these units, are harmful to national defense, since about one half of the new medical reserve officer personnel is supplied by these units. The society believes that the embarrassment of procuring new medical officer personnel will increase to serious proportions after a few years. Resolutions were forwarded to the war department, the surgeon general of the U. S. Army, the congressmen from Missouri, the American Medical Association, the Missouri State Medical Association, and the directors-general of the American College of Surgeons and the American College of Physicians.

NEBRASKA

Society News.—A symposium on diabetes formed the program of a meeting at Wahoo, November 19, of the Sixth Councilor District Medical Association. Speakers were Drs. Frank M. Conlin, Esley J. Kirk, William H. Stokes and Alfred J. Brown, all of Omaha.

Western Clinical Assembly.—The Eleventh and Twelfth Councilor District Medical Societies sponsored the Western Nebraska Clinical Assembly at Sidney, November 12-13, in conjunction with the Western Nebraska Dental Society. The program included the following speakers:

Thomas P. Mullins, D.D.S., Chadron; Ira C. Brownlee, D.D.S., Denver, and Dr. Frank Lowell Dunn, Omaha, Oral Infections.
Dr. Sanford M. Withers, Denver, Practical Considerations in the Treatment of Cancer.
Dr. Thomas D. Cunningham, Denver, Allergy in General Medicine.
Dr. John R. Nilsson, Omaha, Traumatic Surgery.

NEW JERSEY

Society News.—Dr. Eldridge L. Eliason, Philadelphia, was the speaker at a meeting of the Cumberland County Medical Society, October 9, on "Surgical Emergencies of the Abdomen."—Dr. George W. Crile, Cleveland, addressed the Atlantic County Medical Society, Atlantic City, November 9, on "The Adrenal Sympathetic System and Its Diseases."—A symposium on maternal mortality was presented before the Camden County Medical Society, Camden, December 4, by Drs. Frank L. Kennedy, Frank M. Moore, Albert B. Davis and Gordon F. West. Dr. Hyman I. Goldstein spoke on "Liver Therapy in Anemia."—Dr. Francis Ashley Faught, Philadelphia, addressed the Hudson County Medical Society, November 7,

on "Medical Practice Under State Medicine in the United States."—Dr. George M. Levitas, Westwood, addressed the Bergen County Medical Society, Hackensack, December 11, on "Important Biological Factors in Fertility and Sterility."—Drs. Frederic Maurice McPhedran and Eugene M. Landis, Philadelphia, addressed the Burlington County Medical Society, Mount Holly, recently, on "Childhood Tuberculosis" and "Practical Application of Recent Experimental Work on the Circulation and Blood Vessels," respectively.

NEW YORK

Accident Death Rate.—New York's death rate for accidents in 1933 was 68.1 per hundred thousand, the lowest except for one year since 1907, the first year in which statistics of accidental deaths were tabulated. Mortality from automobile accidents held first place, followed in order by drowning, burns, poisonous gases and railroad accidents. Of the 4,671 deaths upstate for which the type of accident was known, 37.9 per cent were motor vehicle accidents, 33.8 per cent home accidents, 18.9 per cent public (exclusive of motor vehicle) and 9.6 per cent industrial (exclusive of motor vehicle).

Institute on Conservation of Vision.—Dr. Harry S. Gradle, Chicago, delivered an address on prevention of blindness, November 6, before a joint meeting of the Onondaga County Medical Society and the Syracuse Eye, Ear, Nose and Throat Club, held in conjunction with an eye institute arranged by the state commission for the blind. The institute, which continued through November 6 and 7, was the third of its kind in the state held for the purpose of increasing the knowledge of lay workers, public health and school nurses, teachers and social workers of eye conditions and to give them an understanding of their significance. The program included papers on anatomy of the eye, nutrition in relation to the eye, errors of refraction, the art of illumination, education of the visually handicapped, and adequate care and follow up of eye cases. Dr. William F. Snow, New York, director of the American Social Hygiene Association, summarized the program at the end.

Plan to Reduce Mortality Rate.—A committee of the Medical Society of the County of Erie, appointed in April 1934 to investigate maternal mortality rates and institute measures to reduce them, made a report at a meeting of the society, November 19. In view of various detailed investigations that have been made, the committee decided not to make a local survey but to put into effect recommendations growing out of other surveys with such local modifications as may be necessary. It is planned to appoint within a few weeks a committee on obstetrics with an associate group made up of representatives of the Buffalo Health Department, Buffalo Academy of Medicine, University of Buffalo, Buffalo Council of Social Agencies, Child Welfare Committee, Visiting Nurse Association, Junior Chamber of Commerce and Buffalo Foundation. Plans for action will include the following features: education of the public, improvement of medical obstetric practice, improvement of hospital standards, the amending of the birth certificate to include information on type of delivery, and supervision of midwives.

Society News.—Dr. Richard Kovacs, New York, addressed the Sullivan County Medical Society, Monticello, December 12, on physical therapy in gynecology.—Dr. Joseph Earle Moore, Baltimore, addressed the Niagara County Medical Society, Lockport, November 16, on "The Wassermann-Fast Patient."—Drs. William P. Healy and George T. Pack, New York, addressed the annual meeting of the New York State Committee of the American Society for the Control of Cancer at Rochester, December 11, on "Diagnosis and Treatment of Uterine Cancer" and "Recognition and Curability of Gastric Cancer," respectively.—Dr. Louis W. Sauer, Evanston, Ill., addressed the Buffalo Academy of Medicine, December 12, on "Whooping Cough—Early Diagnosis, Prevention and Treatment."—Dr. W. Russell MacAusland, Boston, will give an address, January 8, in Buffalo before a combined meeting of the Medical Society of the County of Erie, the Buffalo Academy of Medicine and the Eighth District Medical and Dental Societies, Buffalo Dental Association, on "The Importance of the Oral Cavity in General Health and the Far Reaching Consequences of Abnormal Mouth Conditions."

New York City

Health Demonstration Turned Over to City.—The Bellevue-Yorkville Health Demonstration, established ten years ago as a model for neighborhood health work, was turned over to the department of health, November 15. It will be maintained as a district health station, Commissioner Rice said.

Gifts to Columbia.—The following gifts for medical purposes were recently announced by Columbia University:

Udo M. Reinach, to establish the bulletin of the Neurological Institute Fund, \$2,500.

Columbia University Club, for scholarships, \$2,000.

National Tuberculosis Association, for research in tuberculosis, \$1,020.

The late Dr. Cornelius G. Coakley, for research in otology, \$1,000.

National Oil Products Company, \$500 for research in food chemistry directed by Henry C. Sherman, Ph.D., and \$300 for research in chemical pathology.

Eli Lilly and Company, for chemical pathology research fund, \$600.

Course in Forensic Medicine.—A new course in forensic medicine designed primarily for physicians now holding positions as coroners' physicians or for those who wish to prepare themselves for such work is announced by New York University and Bellevue Hospital Medical College, to begin early in 1935. Formal instruction, occupying the morning hours during two semesters of five months each, will include conferences and work in the pathologic and toxicologic laboratories of the chief medical examiner of the city. The course will be supervised by Dr. Charles Norris with the assistance of Alexander O. Gettler, Ph.D., and Drs. Douglas Symmers, Harrison S. Martland, Armin V. St. George, Thomas A. Gonzales, Benjamin M. Vance, Milton Helpner and Kurt Landé. A long course in forensic medicine, inaugurated this year, covers a period of from three to five years.

Health and Hospital Budgets Reduced.—When the board of aldermen adopted the city budget for 1935 at a meeting, December 3, the estimates submitted by the health department and the hospital department were seriously reduced, the *New York Times* reported. Eight new persons were requested for the staff of the health department, most of them to be full time directors of the several services. Several other positions were eliminated. The department of hospitals also requested salary increases in order to provide full time pathologists and roentgenologists for the city hospitals. The New York Academy of Medicine and the United Hospital Fund held special meetings protesting against the cuts made by the aldermen. The academy pointed out in a resolution that the health department budget had already been reduced to a minimum and asserted that the work would be crippled to a degree out of proportion to the economy achieved. The resolutions urged the mayor to veto the budget as submitted.

NORTH CAROLINA

Society News.—Among speakers at a meeting of the Fifth District Medical Society, Sanatorium, October 18, were Drs. Jabez H. Williams, Sanatorium, on "Surgery in the Treatment of Tuberculosis"; Joseph Rush Shull, Charlotte, "Roentgen-Ray Treatment of Hodgkin's Disease," and Hamilton W. McKay, Charlotte, "Relief of Retention of Urine."—Dr. George E. Pfahler, Philadelphia, addressed a meeting of the North Carolina Radiological Society with the Forsyth County Medical Society, October 20, on epithelioma of the skin, and Dr. Clayton W. Eley, Norfolk, Va., demonstrated ventriculograms.—Dr. George R. Livermore, Memphis, Tenn., was guest speaker at the annual meeting of the North Carolina Urological Association at Winston-Salem, October 24, on "Stone in the Kidney."—Speakers at the regular meeting of the Catawba Valley Medical Society, Lincolnton, November 14, were Drs. Lester A. Crowell Jr., Lincolnton, on "Pneumothorax in the Treatment of Lobar Pneumonia"; Edith A. Goodwin, Morganton, "Treatment of Pneumonia in the Home," and Alfred A. Kent Jr., Granite Falls, "Pneumonia in Childhood."—Dr. Frank Howard Richardson, Brooklyn, addressed the Buncombe County Medical Society, Asheville, November 5, on "Emotional Developments in Children: Some Mechanisms." Dr. Charles Hartwell Cocke, Asheville, addressed the society, October 1, on "Leukopenia in Tuberculosis."—Dr. Isaac H. Manning, Chapel Hill, addressed the Mecklenburg County Medical Society, Charlotte, October 2, on hospital insurance.

OHIO

Hospital News.—A new tuberculosis hospital which is shortly to be built in Lucas County is to be named for William W. Roche, for many years a political reporter on the *Toledo News-Bee*, it was announced after Mr. Roche's recent death. Mr. Roche is credited with having instigated a reorganization of the county hospital about twenty years ago. The hospital is to be built as a FERA project.

Society News.—Dr. Leonard G. Rowntree, Philadelphia, addressed the Academy of Medicine of Cleveland, December 21, on "Therapeutic Application of Newer Developments in Endocrinology."—Dr. Irvin Abell, Louisville, Ky., was guest speaker at a meeting of the Cincinnati Academy of Medicine, December 3, on "Diverticulitis and Diverticulosis of the Gastro-

Intestinal Tract." The academy joined the Cincinnati Dental Society in a meeting, December 7, at which the speaker was Dr. Robert H. Ivy, Philadelphia, on "Care of Injuries to the Face and Jaws."—Dr. Lloyd B. Johnston addressed the Cincinnati Obstetrical Society, December 13, on "Late Surgical Treatment of Uterine Inversion."—Dr. Abram L. Van Horn, chief of the division of child hygiene, state department of health, Columbus, addressed the Logan County Medical Society, Bellefontaine, December 7, on "Present Problems of Infant Health."—Dr. Ora O. Fordyce, superintendent of the Toledo State Hospital, addressed the Toledo Academy of Medicine, December 7, on mental disease; members of the staff presented a general clinic.

OKLAHOMA

Personal.—Dr. David W. Griffin, superintendent of the Central Oklahoma State Hospital, Norman, was honored at a reception given by the hospital staff and other friends, recently, in celebration of his completion of thirty-five years at the head of the institution.—Dr. John L. Day, Norman, has been appointed superintendent of the State Hospital, Supply, to succeed the late Dr. James W. McClendon.

PENNSYLVANIA

Illegal Practitioner Fined.—Charles Hayssen, Mobile, Ala., was recently found guilty of practicing medicine illegally and sentenced to pay a fine of \$100 and the costs of prosecution and to spend thirty days in the Dauphin County prison.

Philadelphia

Society News.—Drs. Francis G. Harrison and Alexander Randall addressed the Philadelphia Urological Society, December 17, on "Carcinoma of the Sigmoid with Rupture into the Bladder" and "Surgery of the Upper Ureter," respectively.

Hospital News.—The fourth public health talk at Mount Sinai Hospital was given by Dr. Eugene Rush, December 26, on "How to Keep Your Children Healthy." The fifth will be presented by Dr. Sigmund S. Greenbaum, January 23, on "Care of the Skin and Hair."

Personal.—A portrait of Charles H. La Wall, Ph.D., dean of the Philadelphia College of Pharmacy and Science, was presented to the college, December 5, by the artist, Leon A. Spielman, a graduate of the school and a practicing pharmacist.—Dr. Basil R. Beltran has recently received the Palme Académic decoration of the Ministry of National Education of France for services rendered to the French during the World War and to the French in Philadelphia.

SOUTH CAROLINA

University News.—Dr. Frank A. Hoshall, Baltimore, has been appointed assistant professor of orthopedics at the Medical College of South Carolina, Charleston.

Society News.—Dr. Lawrence P. Thackston, Orangeburg, was elected president of the South Carolina Urological Association at the annual meeting in Columbia, October 9. Dr. Montague L. Boyd, Atlanta, was the guest speaker at the meeting.—Drs. Thomas R. Gaines, Anderson, and William A. Strickland, Westminster, addressed the Oconee County Medical Society, October 18, on indications for the removal of tonsils and the technic and management of the operation, respectively.—Dr. Montague L. Boyd, Atlanta, addressed the Columbia Medical Society, Columbia, October 8, on "Malignancies of the Urinary Tract." Dr. Joseph Akerman, Augusta, Ga., addressed the society, September 10, on "Obstetric Superstitions and Traditions."—J. Nelson Frierson, LL.D., Columbia, was reelected president of the South Carolina Tuberculosis Association, which met in Columbia, November 1.

TENNESSEE

Society News.—Dr. Willis F. Manges, Philadelphia, addressed the Nashville Academy of Medicine, November 20, on "The Relation Between Sinus and Lung Infections and Between Sinus and Mastoid Infections."—Drs. Edgar Jones and Clarence S. Thomas, Nashville, addressed the medical society of Benton, Carroll, Henry and Weakley counties in McKenzie, November 15, on diseases of the white blood cells and headaches, respectively.—Drs. Phillip H. Levinson and Jesse B. Swafford were the speakers at a meeting of the Hamilton County Medical Society, Chattanooga, November 22, on "Urinary Urobilinogen: the Value of Routine Estimation" and "Normal and Abnormal Behavior," respectively.—Dr. Tom R. Barry discussed "Urology and the General Practitioner" at a meeting of the Knox County Medical Society,

Knoxville, October 30.—Dr. Sam B. McFarland, Lebanon, addressed the Wilson County Medical Society, December 6, on gastric ulcer.—Speakers at a meeting of the Washington County Medical Society, November 1, Johnson City, were Drs. Emmett E. Byrd, on the physician and his profession; Marvin H. Sandorf, gastric analysis, and Raymond D. Tompkins, heart failure.—Physicians of Dickson, Hickman and Humphreys counties recently reorganized the Tri-County Medical Society, with Dr. William J. Sugg, Dickson, as president, and Dr. Harold E. Paty, Lyles, secretary.—Drs. Cobb Pilcher, Tinsley R. Harrison and John B. Youmans, Nashville, addressed the Montgomery County Medical Society, Clarksville, October 19, on edema.

VIRGINIA

Personal.—Dr. John C. Neale Jr., Hilton Village, has been appointed health officer of Henrico County, succeeding Dr. Ernest L. Stebbins, who recently went to the New York state department of health.

New District Health Office.—The state health department has established a new district office in Abingdon with jurisdiction over thirteen counties. Dr. Edgar C. Harper, Richmond, who was formerly associated with the department in various capacities, will be in charge of the new area beginning January 1.

Society News.—The Southwestern Virginia Medical Society held its semiannual meeting in Radford, recently; among other speakers, Dr. Edmund M. Chitwood, Wytheville, delivered his presidential address on "Infections of the Blood Stream."—Drs. Ernest G. Scott and Hunter B. Spencer were the speakers at a meeting of the Lynchburg Academy of Medicine, October 1; their subjects were "Von Gierke's Disease" and "Roentgen Therapy," respectively.—Dr. Frank B. Stafford, Charlottesville, addressed the Medical Association of the Valley of Virginia, Staunton, recently, on "Upper Respiratory Infections Simulating Tuberculosis."

WASHINGTON

Society News.—Drs. Charles B. Ward and Allison T. Wanamaker, Seattle, addressed the Chelan County Medical Society, Wenatchee, October 17, on "Treatment of Malignancy" and "Relation of Biochemistry to Nose and Throat," respectively.—Speakers at a meeting of the King County Medical Society, Seattle, December 3, were Drs. Torleif Torland and Edwin A. Nixon, Seattle, on "Vaginal Hysterectomy by the Clamp Method" and "Observations on the Treatment of Varicose Veins," respectively. At the meeting November 19, speakers were Drs. Lester J. Palmer, on "Care of the Surgical Diabetic Patient"; David C. Hall, "University Health Service and State Medicine," and Inslee B. Greene, "Medicine at the Crossroads."

PHILIPPINE ISLANDS

Society News.—Drs. Andreas Trepp and Sixto A. Francisco addressed the Laguna Medical Society in San Pablo, September 23, on treatment and prevention of tuberculosis.—The Tayabas Medical Association, a newly organized society, held its first meeting in Lucena, September 3, with Dr. Pedro N. Villasenor as the speaker, on management of dysentery.

Health Commissioner Appointed.—Dr. Jose Fabella has been appointed commissioner of health and welfare of the Philippine Islands. Dr. Fabella is 46 years old and a graduate of Rush Medical College, Chicago, class of 1912. Dr. Fabella and Dr. Jose P. Bantug, of the staff of the bureau of health, were guests of honor at a meeting of the Bulacan Medical Society in Manila, September 8. A reception and dance were given at the Cosmos Club, Manila, October 6, in honor of Dr. Fabella by the Philippine Islands Medical Association, the Colegio Medico-Farmacutica and the Philippine Federation of Private Medical Practitioners.

GENERAL

Bequests and Donations.—The following bequests and donations have recently been announced:

Mount Sinai Hospital, New York, \$25,000 by the will of the late Mrs. Isabella Kritzman; \$1,000 from the late Sydney Ballin.

National Jewish Hospital, Denver, \$4,175 by the will of the late Alexander M. Blumenstiel.

Washington Home for Incurables, Washington, D. C., \$5,000, to establish a cancer ward by the will of the late Mrs. Eleanor Foster Lausing.

Automobile Fatalities in Four Weeks.—The bureau of the census, U. S. Department of Commerce, announces that eighty-six large cities in the United States reported 865 deaths from automobile accidents during the four weeks ended November 24, as compared with 734 for the four weeks ended Nov. 25,

1933. Of the total number 665 occurred within city limits. For the fifty-two week periods ended Nov. 24, 1934, and Nov. 25, 1933, the totals for all cities were 8,822 and 8,077, respectively, which indicate a recent rate of 23.6 per hundred thousand as against an earlier rate of 21.4.

Changes in Status of Licensure.—The Michigan State Board of Registration in Medicine reports the following action:

Dr. Joseph Henry Hanson, Detroit, license restored, recently, for one year of probation. At expiration of this year, final action for complete restoration or revocation will be taken.

Dr. William Kelley, license revoked, recently, for conviction and federal sentence for violation of the Harrison Narcotic Act.

The North Carolina Board of Medical Examiners reports the following:

License of Dr. Thomas Art Smith, Charlotte, restored at its June meeting.

The Oregon Board of Medical Examiners makes the following statement:

License of Dr. George Ernest Darrow, Los Angeles, to practice in Oregon revoked for moral turpitude.

The New York State Board of Medical Examiners reports the following:

License of Dr. Burdette Martin Christianson, New York, restored in September after six months' suspension.

Government Services

Changes in Public Health Service

Surg. Paul D. Mossman, relieved at Ellis Island, N. Y., and assigned to duty at Naples, Italy, in the office of the American consul.

Passed Asst. Surg. Ralph B. Snavely, relieved at Stapleton, N. Y., and assigned at the National Institute of Health, Washington, D. C.

Surg. Mark V. Ziegler, relieved at Raleigh, N. C., and assigned at Washington, D. C.

Passed Asst. Surg. Edwin G. Williams, relieved at Naples and assigned at Ellis Island.

Acting Asst. Surg. Austin H. Smith, relieved at Fort Eustis, Va., and assigned at the U. S. Penitentiary, McNeil Island, Steilacoom, Wash.

Asst. Surg. Bert R. Boone, relieved at Seattle, Wash., and assigned at the marine hospital, Detroit.

Drs. John R. Heller and Charles S. Sample Jr., appointed and commissioned as assistant surgeons.

Drs. Joseph R. Ridlon and Randolph M. Grimm, promoted and commissioned as medical directors.

Food and Drug Seizures for November

Nearly 16,000 bushels of apples bearing poison residues exceeding the limits of safety were seized by the Food and Drug Administration of the U. S. Department of Agriculture during November after they had been shipped from New York, Michigan, Illinois, Missouri and other central states. Fifty-two shipments of cream totaling more than 3,000 gallons, and 11,676 pounds of unfit butter were confiscated and destroyed. Among other seizures were sixteen of canned shrimp, amounting to 4,000 cases; eleven of canned mackerel totaling 4,300 cases. Nineteen shipments of edible oil, 7,000 cans filled with cottonseed oil, corn oil and bean oil with little or no olive oil, were also seized; all were labeled so as to lead a purchaser to believe the products were composed largely or entirely of olive oil or were of foreign origin. In the drug field seizures included shipments of chloroform, tincture of opium and witch hazel extract. Recent prosecutions reported by the administration include: The Oelwein Chemical Company, Oelwein, Iowa, fined \$200 for shipping livestock preparations bearing unwarranted claims of vitamin potency; Natural Products Company, Eugene, Ore., \$900 for shipping misbranded mineral waters; Steketee's Family Medicines, Grand Rapids, Mich., \$200 for shipping "patent medicines" bearing false therapeutic claims, and the Alaska Year Round Canneries Company, Seattle, Wash., \$300 for shipments of canned salmon consisting partly of decomposed fish. Many other fines ranging from \$1 to \$200 were reported.

CORRECTION

Cultivation of the Virus of Lymphogranuloma Inguinale.—In Dr. Elmore B. Tauber's discussion in THE JOURNAL, December 15, page 1833, is the following sentence: "By using a special medium, I think I have succeeded in cultivating this virus." Dr. Tauber writes that this is incorrect and should have read as follows: "I am informing you of the cultivation of a virus, the work of Dr. Joseph Tamura." Dr. Tauber meant merely to call attention to Tamura's work, to whom all credit for this work, he says, is due.

Foreign Letters

LONDON

(From Our Regular Correspondent)

Dec. 1, 1934.

Asthma Research

The Asthma Research Council was formed in 1927 to direct research into asthma and was supported by public subscription. Under the auspices of the council, asthma clinics have been established at some of the principal hospitals. The report for the year ended last October shows that the clinic at Guy's Hospital continues to expand. During the year there were 5,575 attendances and 450 new cases. Such a large number has given a better insight into the natural history of the disease. Dr. L. J. Witts has shown that the most striking difference between the asthmatic and the normal is the high incidence of protein hypersensitivity and the frequency of lesions of the upper and lower respiratory tract. In conjunction with the experimental work of Dr. R. S. B. Pearson, these results have confirmed the value of the skin tests, which at one time were the subject of much criticism. Treatment has been directed to attacking the lesions of the respiratory tract by respiratory exercises, inhalations, vaccines and operations, while the protein hypersensitivity has been dealt with by avoiding the harmful agents and attempts at specific and nonspecific desensitization. Though the essence of asthma still seems to escape analysis, the conviction grows that protein hypersensitivity and respiratory damage are the stimuli that make manifest a biochemical difference between the asthmatic and the normal, which should be susceptible to simple treatment. Dr. Pearson has continued the study of skin tests to common allergens and proved the superiority of the intradermal over the scratch technic of skin testing. It has been found that positive skin reactions are not uncommon in apparently normal persons, so that no sharp distinction can be made by them between the asthmatic and the healthy. It is not hypersensitivity that is pathologic but its persistence in exaggerated degree. Skin tests have shown that the majority of asthmatic persons are sensitive to several proteins, which they are constantly inhaling—house dust, feathers, orris root (face powder), pollens, horsehair and other animal hairs. Concentrated solutions of each have been prepared and reactors have received a course of inoculations. Good results have been obtained, especially with oily solutions and in the predominantly nasal cases. It is recommended that vasomotor rhinitis and paroxysmal rhinorrhea be treated on allergic lines, as relief is quickly obtained in the majority of cases. At St. Mary's Hospital the main treatment has been on bacteriologic lines. A special method has been used whereby the organisms to be incorporated in the vaccine are selected after the bactericidal power of the patient's blood has been tested against the various organisms isolated from the patient. Those which have stood the bactericidal action of the blood are used.

HAY FEVER

The prevention and treatment of hay fever by injection of large doses of grass pollen extract gives relief in nearly 100 per cent of cases. The results are controlled by skin tests and the result aimed at is the complete desensitization of the patient, as indicated by negative skin reactions. The amount of pollen extract required to abolish skin sensitivity and give complete relief varies and frequently necessitates the use of doses of 100,000 units of extracts.

BACTERIAL SENSITIZATION

An experimental investigation is being carried out on the significance and mechanism of the late inflammatory skin reactions to bacterial products seen in cases of bacterial hypersen-

sitiveness. In the past, many workers have investigated sensitiveness to bacteria and their products but so far the mechanism of induced sensitization and the production of inflammatory skin reactions are by no means clear. It is thought probable that active antibacterial immunity and hypersensitivity to bacterial products are brought about by two distinct portions of the bacterial cell. Dr. Harley has shown that the immunizing antigen of pneumococci can be obtained free from bacterial protein and other cellular substances and that this is the portion of the pneumococcus responsible for the production of immunity. It appears that sensitiveness to bacteria is not induced by the immunizing antigen but by the bacterial protein and that the animal sensitized by either the whole organism or the bacterial protein reacts to these but not to the isolated immunizing antigen; conversely, treatment of an animal with the isolated antigen produces immunity but not hypersensitivity to the organism. It is thought that the final results of this investigation will have considerable bearing on the treatment of bacterial hypersensitivity.

Pay for the Treatment of Road Accidents

According to the new road traffic act, in case of bodily accidents (including fatal injuries) the person using the vehicle that caused the accident must pay the physician rendering emergency treatment a fee of \$3 for each patient and a mileage fee of 12 cents a mile for any distance over 2 miles. If more than one physician administers treatment, the first to do so will be entitled to make a claim. The same payments must be paid to hospitals that render these services. If the accident is due to the negligence of some party other than the vehicle user, the latter is entitled to recover from the former the amount payable to the physician or hospital. The act has also been made water tight as regards insurance companies which issue various restrictions in their policies, such as that a car must not be used for business purposes and then decline to pay under these circumstances. In future it will be the duty of the insurance company to pay for all third-party risks, and any limitations contained in a policy as to age, physical condition of the driver or other conditions will be void. This means that the insurance policy of the user of the vehicle (which is compulsory) must cover such third-party risks.

The Protection of Radium Workers

At the British Institute of Radiology, Dr. G. W. C. Kaye, director of the physics department of the National Physical Laboratory, made a communication on the protection of radium workers. The two main factors of gamma ray protection are to place the radium source as remote as is feasible and to enclose it in protective material. To double the distance from the source is equivalent to increasing the lead protection by nearly 3 cm. But in many cases there is no alternative to lead protection, and for this a transmission curve of gamma rays in lead under conditions as near as possible to those of practice has been worked out at the National Physical Laboratory and leads to the following practical conclusions: The tolerance distance for unprotected radium of 0.2 Gm. and upward is greater than the distance between adjacent beds in a ward, so that precautions should be taken if patients undergoing irradiation are in the same ward as other patients. For nurses and other attendants the tolerance distance for 0.2 Gm. of unprotected radium is about 2 meters, so that they should approach within that distance only when necessary. For quantities of 0.5 Gm. the tolerance distance is 3.5 meters. Therefore the staff should not remain in the vicinity of patients undergoing treatment with such quantities. The carrying boxes used for transport of radium of ordinary amounts are usually small and made of wood, lined with lead of 1 cm. thickness. These are suitable for occasional transport of small quantities, but if larger quantities are frequently transported larger boxes,

with centrally situated small containers and more adequately protected, should be provided, and these should be conveyed by trolley rather than by hand. As to transmission by the British parcel post, which has the limitations of 11 pounds in weight and 6 feet for length plus girth, it has been found that distance is superior to lead protection. A bulky parcel containing no lead may have only half the weight and be thrice as effective as a small packet with the maximum of lead protection. Moreover, bulky packages are more likely to be transmitted in the post by vehicle than by hand, which is an advantage. With regard to radium beam therapy, nurses and attendants should not remain for any appreciable time at distances within 1.5 meters behind the bomb, 2.5 meters from the side of it, or 4.5 meters in front of it, in the direct beam.

Congress on Colon Bacillus Infections

It is the custom in France to hold meetings at the various resorts at which the springs have medicinal virtues. At these meetings the most distinguished members of the profession are invited to read papers describing their experience with diseases that the particular spring aims to relieve. Chatel-Guyon, in the center of France, is noted as a resort that specializes in the treatment of gastro-intestinal ailments. Like most of the large medicinal watering places in France, it is well organized so far as medical supervision and physical therapy are concerned.

An instructive paper read at the Congress on Colon Bacillus Infections recently at Chatel-Guyon was by Noel Fiessinger and Hutet of Paris. Attention was called to the danger of making the colon bacillus responsible for too many conditions until proof had been given of such etiology. No one can deny that infection of the urinary tract due to the colon bacillus exists, but to employ too easily the term "colibacillosis" for infections of the alimentary tract, even though they are of mild character, as well as for fevers of undetermined etiology, is not warranted by the facts. This is especially true of colon bacillus infections of the urinary tract. Here the colon bacilli, which are present normally in the lower alimentary tract, are supposed to traverse the intestinal wall and the portal and pulmonary circulations, to be finally eliminated through the kidneys. There has been no proof of this in the form of a positive blood culture. The authors of this rather frank criticism have sought in vain a colibacillemia in persons suffering from constipation. Only in two severe cases of septicemia due to the colon bacillus was the blood culture positive. The passage of the bacilli from the colon into the circulation occurs but rarely. If the organisms were in the blood, they could not escape detection by culture methods.

Colon bacillus infection of the urinary tract is quite common in women without any accompanying symptoms. One must take every precaution in securing urine for bacteriologic study, because the normal urine is constantly infected by the colon bacilli in the vulva, even after a catheterized specimen has been obtained. The only way to decide whether such a contamination has taken place is to inoculate culture mediums within an hour after the specimen is obtained. Even with these precautions, cultures were positive without any accompanying symptoms. The female urethra, on account of its relatively small size, constantly allows growth of colon bacilli. This does not occur in the male urethra. The presence of colon bacilli in the urine therefore is not synonymous with infection of the urinary tract by these organisms. The authors are opposed to the theory of Heinz-Boyer that the colon bacilli traverse the intestinal wall. The real factor that aids the development of the colon bacilli in the urinary tract is the

oliguria that occurs at the beginning of menstruation. This favors the growth of the organisms in the urine. In the enterorenal syndrome it is the decreased absorption of fluid that is lacking and not an infection of the blood by the colon bacilli from the intestine. A colon bacillus septicemia is an effect and not a cause of the urinary tract infection.

The only other colon bacillus infection is that which involves the gallbladder. It is not due to an ascending infection along the common duct from the duodenum. The authors have observed a colon bacillus cholecystitis in only two fifths of their cases, never in cases presenting urinary infection with colon bacilli.

The conclusions reached by these authors are contrary to those of many French clinicians, that in the majority of cases colibacillosis is a local and not a generalized infection. The more normal the digestion of food, the more colon bacilli one finds in the stools.

In severe enterocolitis, typhoid, cholera and dysentery the number of colon bacilli in the intestine decreases in proportion to the increasing gravity of the disease. When the colon bacilli begin to grow again on culture mediums, the disease is near its end.

The elimination of obstructions in the urinary tract and large quantities of fluid will do more to eliminate colon bacillus infections than any other treatment.

Suicides of the Adolescent

An instructive survey of the causes of the increasing number of suicides of the adolescent is contained in an article of Dr. Gilbert Robin. One reads articles by psychiatrists in which the causes are given as melancholia, epilepsy or dementia praecox. This is far from explaining the majority of cases. Adolescence is the period of life in which the parents, if they wish to give any advice, should never use harsh measures in the form of commands or injunctions. There is revolt and an inevitable struggle on the part of the recipient, whose personality at this period is too strong for the world, which is opening its doors to assimilate them. The point of view of the adolescent is not that of the adult. The adolescent believe themselves to be heroes and hence there arise misunderstandings between them and adults. According to Robin, it is the contact of this intense personality, which considers that it cannot live in the adult world and seeks any means to avoid it, which plays the leading part in suicides of the adolescent. In some cases the contrary occurs. The personality is groping to find its place in organized society and it is at the end of a fruitless search. Others become too introspective, regarding themselves for hours in a mirror, in the effort to find in the physiognomy the reflection of the movements of the soul. They overlook the real appearance to come into contact with an unreal personality. Among the adolescent there are those who commit suicide because of an exaggerated sense of honor, which they flatter themselves that they possess, often to merit, post mortem, the appreciation which they considered that they were entitled to during life. They believe that in committing suicide they are inflicting punishment on those who failed to appreciate their merits during life.

Other causes are found in two extremes of society, those who have been raised in poverty and have never seen the brighter side of life, and, at the other end of the scale, those who have had parents too rich or too cowardly to refuse anything, wherefore every thrill has been exhausted and there is only ennui left.

Experimental Production of Actinomycosis

In the *Annales de l'Institut Pasteur* for September, Grooten reports the results of successful experiments made to determine whether human actinomycosis is transmissible to rabbits. The organisms were isolated from two cases of the disease in

the human jaw and one in the neck. The cultures incorporated in Veillon gelatin were injected into the peritoneal cavity of rabbits. The gelatin seems to protect the organisms from attack by the polymorphonuclear leukocytes sufficiently long to combat phagocytosis. It requires several months for the typical yellow granules to develop.

Antistreptococcus Serum of Vincent in Obstetrics

The subject chosen for his graduation thesis by Brimon-Cherbuliez was the antistreptococcus serum of Vincent in obstetrics. The work reported was based on twenty-seven cases observed in the Maternity Department of the Boucicaut Hospital. The serum has been employed in cases of septicemias with positive blood cultures as well as in septicopyemias and other prolonged postpartum infections. If given in sufficiently large doses and over a long enough period, as emphasized by Vincent, the results will be gratifying. The only failures were in cases due to other organisms than the streptococcus.

As a prophylactic measure, the serum ought to be given in all cases of hemorrhage due to placenta praevia or other uterine lesions, as well as in those in which there are retained cotyledons or membranes, in amniotic infections, in endometritis, in acute sore throat, in influenza, in intra-uterine intervention or in artificial delivery. In these cases, 20 cc. should be given daily for three days.

The percentage of postpartum infections following intra-uterine operations during delivery has fallen from 30 to 15 as a result of the prophylactic use of the Vincent serum.

Immunity of Cubans to Yellow Fever

At the November 6 meeting of the Academy of Medicine, A. Recio presented an interesting paper based on the examination of the blood of Cuban natives (black and white) born before or after the last epidemic of yellow fever; i. e., since the last case was reported in 1908. Of sixteen individuals born prior to 1901, the date of the last severe and generalized epidemic, twelve, or 75 per cent, were found to be immune. Of eleven persons born between 1902 and 1908, during which interval there were small localized epidemics, none were found to be immune. The same was true of fourteen others, born since 1908, since which date no case has been reported.

In the discussion, Dominguez emphasized the importance of Recio's study. Up to the present time the native Cuban has always been regarded as immune to yellow fever. If another epidemic occurred, the majority of the Cubans would be just as susceptible as those not born there.

Congress of German Ophthalmologists

At the recent fiftieth Congress of German Ophthalmologists, Best spoke on hereditary glioma of the retina, which sometimes may be dominant, other times recessive. The importance of heredity must not be overemphasized, since most children having glioma die before the age of puberty and, above all, since 85 per cent of cases are unilateral, despite the influence of heredity, which is essentially the same in the eyes of twins. Others found that, of forty-eight cases of glioma, twenty-seven showed no hereditary factors or influence from familial intermarriage. The occasional familial event of a phenotypic healthy married couple whose children all suffer from glioma certainly points to hereditary influences. In such cases the glioma is mostly bilateral. The lack of heredity in sporadic cases as well as the frequency of it in familial cases may be explained by mutation. Families presenting glioma are otherwise hereditarily healthy, so that a combination with any other gene is not to be taken into consideration. According to Best, the mendelian laws do not definitely apply to gliomas and to other

severe ocular deformities. Sterilization should be done in clear sporadic cases.

Serr reported on autohemic injections into the anterior chamber in tuberculous iritis according to Schieck. He found a rapid improvement of clinical symptoms in thirty-two eyes and in five after continued treatment. Permanent results were generally satisfactory. Treatment was unsuccessful in ten eyes, and one patient showed definite deterioration.

Marchesani read a paper on juvenile recurring vitreous hemorrhages, which have heretofore been interpreted as probably of tuberculous origin, in that tuberculosis of the venous walls was assumed. In a number of such cases the author observed signs of thrombo-angiitis obliterans. The anatomic differentiation of a tuberculosis of the veins from other types of vascular changes cannot be definitely made, for giant cells may appear on the vascular walls without tuberculosis.

Schieck spoke about the changes in the vortex veins and vessels of the choroid in glaucoma. The latter are especially widened at the point where they enter the veins, while the lumen of the vortex veins was almost obliterated. A pathologic condition of the wall was no more in evidence than an obstruction of the beginning part of the vessel through the sinus wall; rather, the pressure on the sclera had merely forced the obliquely transpassing veins together.

Several papers treated of operative methods for detachment of the retina. Special attention was given to electro-endothermy. Meesmann of the Berlin Charité Augenlinik improved the method by developing electrodes, which allow an exact measure of the heat produced in the various tissues of the eye, so that mistakes in dosage, caused by the different electrical conductivity of various tissues, can be excluded. The temperature is most effective in an exceedingly low degree; namely, between 158 to 167 F. Heat greater than this may bring about severe injuries, such as intra-ocular hemorrhages, with bad prognosis. Underdosage can be easily avoided.

Mylius maintains that not enough attention has been given to diseases of the eye in renal diseases. Yet there are hardly any symptoms to be found. Eleven cases of benign sclerosis were anatomically without any special symptoms. In twenty-one cases of renal diseases, severe changes in the blood vessels of the ciliary body may be recognized. The following symptoms are worthy of mention: proliferations of the intima from the mildest to the most advanced degree with obliteration of the vascular lumen in addition to simple hyaline and sclerotic degeneration of the vessels, severe hypertrophy of the muscularis, especially swelling, lipid infiltration and disintegration of the wall. Von Hippel was concerned with the subject of bacilemia in diseases of the eye. The results of his tissue cultures which are of great diagnostic value in these cases were:

Of 46 cases of iritis, 12 positive.

Of 1 case of sympathetic ophthalmia, 1 negative.

Of 21 cases of perivasculitis of the retina, all negative.

Of 19 cases of retrobulbar neuritis, 6 positive.

Of 27 cases of other diseases, including scleritis, interstitial and phlyctenular keratitis and choroiditis, 6 positive.

Of 11 cases of perforated injuries, 3 positive.

With respect to the successful treatment of sympathetic ophthalmia, von Szily performed grafting experiments on chickens and monkeys as well as further transplantation from animal to animal. He obtained new specific results, among which round cell clusters predominated to the point of building real lymph follicles. The supposedly specific virus is ineffective on the cornea as compared with herpes virus; it does not spread diffusely through the central nervous system and does not produce encephalitis or any otherwise general symptoms. There are many differences of opinion regarding the histology of sympathetic ophthalmia in human beings. A specific pathologic agent probably lies at the bottom of this disease.

Incidence of Cripples

A census taken for all of Germany in 1906 showed that 1.48 per cent of every 1,000 inhabitants are crippled children. The difficulty of accepting such statistics begins in definitions. According to Dr. Landwehr of the Municipal Health Department of Cologne, cripples are persons "who as a result of abnormalities of the motor apparatus are so permanently injured in using it that their ability to compete in the working market and earn a living is diminished."

The national census of cripples for 1925-1926 gives as the total number of cripples around sixty to every 10,000 inhabitants (without including those injured in the war); of these almost two thirds are classed as severely crippled. The severely injured are defined as "persons whose normal motor ability has been permanently impaired or whose body form deviates strongly from the norm." It is difficult to determine the amount of orthopedic defects in the population and it is almost impossible to evaluate them, especially because in cripples the interrelation of the factors producing the irregularity are more varied than in any other field of social biology. In 1932 and 1933 Dr. Landwehr classified 2,500 cases of the Public Welfare Office in Cologne. These statistics comprise only children and young people up to 25 years of age, including weak minded and mentally unbalanced patients. Of these cases, 16 per cent were minor impairments (syndactylia, slight foot or spinal deformities), 40.2 per cent of the patients were crippled (that is, with recent bone tuberculosis, severe curvature of the spine, deformities of the large joints, loss of a limb, and some were in need of institutional care); 43.8 per cent were still under observation. From the sociological point of view, 18.3 per cent of 2,500 people under welfare station care are classified as severely crippled; of these, 10.3 per cent are unable to walk; 20.7 per cent evinced a high degree of kyphosis; this group includes patients presenting internal injuries and fistulas, and dwarfs; 14.7 per cent showed arm impairments such as stiffening of the large arm joints in an unfavorable position, complete paralysis of these joints and severely mutilated hands; 16.4 per cent are one handed and have arm and hand paralyses that are attributable to the loss of the hand; 37.9 per cent show such leg abnormalities as unsteady, dragging walk, and congenital and spasmodic paralyses; this also includes persons with bulky prostheses. At this point it should be mentioned that body injuries, as the loss of an arm dating from birth, so seldom offer physical difficulties to the persons afflicted that many of them are capable of normal business occupations. The number of congenital cripples varies. In a census taken in one of Berlin's larger districts, for example, the total number of cripples amounted to 5.5 per cent, whereas the national census of crippled children and adults up to 20 years of age is 32.9 per cent and in the advanced age groups 16.6 per cent. Therein lies the great tendency to assume in young cripples the presence of a birth injury, although it may not have been proved. Closer analysis might reveal that 16 per cent of "congenital defects" more closely approaches the true situation and is perhaps the minimal estimate.

Campaigning for Deliveries at Home

A decree of the Prussian minister of the interior concerning the problem of deliveries at home and deliveries in special institutions is an interesting contribution to the new racial policy in Germany. Numerous and various organizations together with wide sections of the population interested in increasing the birth rate have recently taken great pains to prevent deliveries in obstetric homes or clinical institutions as far as possible in order to reduce the death rate of mother and child. This conviction is based on the idea that the fundamental transference of all births to lying-in institutions is a necessary measure. According to the minister of the interior this point of view does not agree with present-day experiences

in medicine. Clinical delivery is naturally to be recommended in every case in which complications are expected or in which living conditions are especially unfavorable. On the other hand, recent scientific investigations and experiences have revealed that the chances for a favorable and normal course of delivery are no less in one's own home than in a clinical institution. The only disadvantage attendant on a delivery at home is that when an emergency operation is needed it may be too late to call a doctor or too late to transfer the patient to a hospital. But there are advantages worth mentioning, such as the uninterrupted care by the same midwife, the gradual transition from puerperal bed to house work, and the valuable experience of learning how to relax. The transition from clinical care to house work is often marked by unfavorable effects. The danger of puerperal fever or other infectious diseases is generally no greater for the mother in a delivery at home than in an institution. Furthermore, confinement at home makes the members of the family feel closer to one another, which agrees with the National Socialist program of life, whereas the attempt to transfer all confinement cases to institutions would in many ways produce a sense of familial estrangement. Finally, the support of medically unimportant institutions is a double burden to the community in that it is necessary to tax public funds to keep them up and that it imposes on the time and services of all available competent physicians, midwives and nurses. After all, the establishing of any non-self-supporting lying-in homes should in any case be opposed and the demands made by such established homes should be carefully examined from this point of view. The tendency to transfer puerperal patients to institutions should be discouraged unless on expert advice.

Campaign Against Tuberculosis

The tuberculosis societies of Germany united in a congress for the promotion of health, held during September at Salzflun, a German spa. Among others, Dr. F. Kreuser of Stuttgart read a paper on tuberculosis as a vocational disease. With respect to the incidence, it may be said that there are only a small number of cases presenting occupational infection. However, active tuberculosis infection must be guarded against in the future by having applicants for work submit to a thorough physical and roentgen examination. Likewise, roentgenograms should be made of the personnel during and after periods of exposure to infection. In addition to instructing the attending personnel, attention should be focused on procuring healthy working conditions in every locality. For those afflicted with disease and those who have become rehabilitated, a work adjustment board should be established, which would not permit completely healthy people to work side by side with their sick co-workers.

The connection between women workers and tuberculosis was discussed by Dr. A. Hofbauer of Erfurt. The unfavorable effect of industrial work on tuberculosis in women is generally caused by burdensome work. Especially deleterious effects are produced in women who have a double task to perform; namely, the duties of mother and housewife as well as those of daily wage earner. Women should be eliminated, especially from dusty occupations. An increase in tuberculosis of women would result in racial deterioration.

H. Krusch of Gotha commented on the conducting of medical examinations in the tuberculosis public welfare stations. The state of Thuringia is an example of what a well conducted public welfare office can do. Each principal attending physician in 1932 had on an average of 5,000 roentgenoscopies (388.8 to every 10,000 inhabitants) and about 4,500 physical examinations (386.7 to every 10,000 inhabitants), sometimes even more. Dr. Krusch believes that it is necessary to follow up all those in the neighborhood of cases of open tuberculosis by thorough roentgen examination. The understanding of the "neighbor-

hood" should be further widened so that the neighborhood of recently appearing closed tuberculous patients should be investigated. Immediate examination of all collaborators is important; the greatest danger of infection in conditions of bodily strain lies in the close contact between workers. One will always find fewer cases of open tuberculosis in the environmental than in the serial examinations. Here lies the importance of the environmental examination, which the smaller dispensaries are in a position to conduct, while the making of serial roentgen examinations requires an elaborate technical and medical set up.

A decree of the Prussian Ministry of Science, Art and Popular Education concerns the protection of school children against any danger to their health from tuberculous teachers. The reports of official physicians required with the application for entrance into the normal school during the course of study there and on assuming regular employment must be accompanied by a roentgen examination of the lungs. The minister adds that experience has proved that these conscientious evaluations of roentgenologic examinations afford an effective protection against tuberculosis in school children. The demand for roentgenograms is also conducted in an economical fashion, so that the costs of paper films come to only 0.40 R. M. Despite the careful observation and elimination of applicants for teaching positions, special attention must be applied to the danger of tuberculous diseases in all classes. It should be the duty of the school board to demand a facsimile of a certificate of health from an official physician or even from a specialist in cases suspected of tuberculous infection or of tuberculous invasion; as soon as the disease manifests itself, proper measures should be instituted.

Infection Due to Bang's Bacillus

From Oct. 1, 1932, to Sept. 30, 1933, 483 cases of infection due to Bang's bacillus were reported in Germany. Of these, 350 were in men, 131 in women, and 2 undetermined. Diagnosis was made on the basis of serologic examinations of the patients. During the three years previous the number of cases reported were as follows: 1929-1930, 626; 1930-1931, 520; 1931-1932, 498. Most cases occurred in middle aged patients. No cases of infection from Bang's bacillus in connection with abortion were observed. Those reported were always individual diseases; transmission of infection from person to person was not observed in one instance. Of four deaths observed, only one was directly attributable to the Bang bacillus infection.

BELGIUM

Radio Medical Consultations on the High Seas

As a consequence of the initiative of Dr. Bernard, mentioned in a former letter, the service of radio medical consultations on the high seas has been developed considerably. The journal *Wandelaar*, published under the auspices of the navy, reports that since 1927 twenty-three nations have given their adherence and as a result ninety-three coastal stations have been equipped. The complete list is given in the fourth edition of the Nomenclature of Berne (international telegraphic bureau), which has just appeared. Besides Belgium (one station, Ostende-Radio), France (six stations), Germany (two stations), England (ten stations), Holland (one station), Norway (three stations), Sweden (five stations), Ireland (two stations) and Denmark (two stations), one finds also Australia (fourteen stations), Colombia (one station), Costa Rica (one station), the United States (twenty-five stations), Fiji Islands (four stations), Guatemala (one station), Honduras (three stations), Marianne Islands (one station), Marshall Islands (one station), Nicaragua (three stations), New Guinea (one station), Panama (two stations), territory of Papua (one station), Samoan Islands (one station), Faeroe Islands (one station) and Greenland (one

station). The Pacific has been especially equipped, while the South Atlantic has not yet been equipped but is supplied by the continuous increase of short wave stations. As to the English Channel and the North Sea, the vessels have at their disposal the stations of Boulogne-sur-Mer, Ostende, Scheveningen and North Foreland; the largest part of the radiomedical traffic is handled by the latter station. The English service is distinguished by the fact that a vessel may request a maritime sanitary office from the shore on the condition that it comes to anchor at three miles from the coast ($5\frac{1}{2}$ kilometers).

Pulmonary Anthracosis

Dr. Courtois brings an important contribution to the question of anthracosis-silicosis-tuberculosis. Being the physician of a sanatorium, of an antituberculosis dispensary, and of a consultation clinic of the respiratory passages, situated in the middle of a mining region, the author had occasion to study the history of 136 miners suffering from pulmonary disorders. He describes the symptoms of the disease and then presents a number of cases of miners suffering from pulmonary diseases, with reproductions of the roentgenograms of the thorax. Among the 136 patients, twelve present disorders of no medical interest, thirty-three present so-called negative roentgenograms belonging to the "anteprimary" stage of the disease; ninety-one present so-called positive roentgenograms, of which thirty offer nodular opacities (primary stage), and sixty-one confluent opacities (secondary stage).

Courtois presents pathologic microscopic and macroscopic documents of great value and shows what he calls "the film of anthracosis." Anthracosis presents an anteprimary stage characterized by a slow and progressive invasion of the lungs by coal dust mixed with siliceous and other elements; the primary stage, besides roentgenologic signs, manifests itself by cardiopulmonary disturbances, and in the secondary stage the fibrosis, nodular in the beginning, becomes confluent. The second period is the time of the infectious complications, especially tuberculosis. In his statistics Courtois finds that more than one fourth, even two fifths, of the patients suffer from tuberculosis, and it is here that the conclusions of the author are unexpected and interesting because they do not agree with the ideas generally held on the subject of tuberculosis among miners.

Twenty-Sixth Congress of the Belgian Medical Federation

The twenty-sixth Congress of the Belgian Medical Federation has been held this year under the presidency of Dr. Mattelet and studied some interesting questions.

If a physician makes a discovery has he the right to reserve for himself the monopoly of it? The president, Dr. Mattelet, discussed this question following an inquiry instituted by the International Professional Association of Physicians. A study has been made through the intervention of the League of Nations, in order to elaborate a new international convention protecting the patent of invention and the scientific property. It is necessary that the medical profession make known its point of view so that it may be taken into account for any convention that might eventually be signed. The reporter thinks that in principle the medical patent can only harm the reputation of the medical profession, which in any case should keep intact its traditional virtues. Consequently, the physician should not take a patent for any discovery that may render service to humanity. It follows that an international action should be taken for the abolition of any patent of medical nature taken by a physician or a nonphysician. If under certain conditions and for certain uses it should be decided that a patent should be taken, it is desirable that such patents be dedicated, in other words, exploited by a governmental or scientific organization (the Order of Physicians, Academy, and so on), especially

the public interest being taken into account. The proceeds should for the largest part go to a foundation for scientific research and some part could be used to reward the author of the discovery proportionately to its importance and utility.

Functions of Subcutaneous Tissue

Dr. Casazza of Pavia recently reported to the Società Medico-chirurgica of Pavia on his investigation of the function of absorption of the subcutaneous tissue, especially from a dermatologic point of view. While some authors have investigated the function of absorption of the subcutaneous tissue in cardiac defects and in renal diseases to ascertain the influence of the latter on the former as a repercussion, the speaker's work is an attempt to verify the local phenomena that may have a direct influence on those functions. He performed Donath and Tanne's test of uranin injection, which permits a good estimation of the absorption, in 125 patients suffering with different dermatologic conditions. He concludes that each individual reacts to the test in a constant personal way, that grave local lesions of the tegument may have an influence on the absorption of the subcutaneous tissue, and that the characteristics of absorption are different for each individual.

Microbes in Bile

Dr. Sciuti of Catania recently reported his experiments performed to ascertain whether or not bacteria are present in the bile of the normal gallbladder. While some authors state that bile not only is sterile but possesses antiseptic properties, others state that only the bile of the intrahepatic ducts is sterile and that the bile of the gallbladder and of the middle third of the common bile duct is contaminated by bacteria. The speaker determined the bacterial contents in common and centrifugated bile from normal gallbladders of twelve dogs and thirty-four oxen. He concluded that bile from living animals, as well as that taken immediately after the animal has been killed, frequently is contaminated by either colon bacilli or staphylococci. A condition of latent microbism was found in the bile content of normal gallbladders in the majority of the animals. The anatomic conditions of the gallbladders from which the bile was obtained indicated that the latent microbism does not provoke, as a rule, noticeable pathogenic symptoms.

Cisternomalarial Therapy

Drs. Mariotti and Sciuti recently reported to the Academia delle Scienze Medico-Chirurgiche of Naples the results of their work on malarial therapy in dementia paralytica. Having in mind the good therapeutic results obtained from the injections of malarial blood into the spinal cavity, so as to have closer contact between the spirochetes in the neuraxis and the malarial virus, they injected malarial blood into the cisterna magna in sixteen patients with dementia paralytica, all in advanced stages of the disease. Obrega and Esckuchen's technic was followed. All patients, even those who had resisted other methods of malarial therapy, reacted, after a period of incubation that was shorter in those who received blood taken during the apyretic period of the malarial patient, with intense fever. The condition did not change in four patients; one died in about three months after the treatment, and the remaining patients were improved. They believe that cisternomalarial therapy is a new and efficient method for the treatment of dementia paralytica. They also believe that this method is better than that of Ducosté and his collaborators, who injected the malarial blood into the white substance of the frontal lobe and in the cerebral ventricles, with an immediate mortality of 9 per cent with the ventricular method.

Mechanism of Fever

Dr. Salmon recently reported to the Accademia Medico-fisica Fiorentina the results of his studies on the importance of the endocrine factors in the mechanism of fever. The nuclei of the tuber cinereum, either because of their vegetative nature or because of their close relation to the endocrine apparatus, have an action of regulation on the body temperature. The fact that the stimulation of the tuber cinereum provokes a hypersecretion of epinephrine (according to Houssay and Molinelli), and the close functional synergy between the tuber cinereum and the posterior lobe of the hypophysis, justify the hypothesis that the sudden reaction of the tuber cinereum by which fever is determined manifests itself with a suprarenal and pituitary hypersecretion. This hypothesis, which would clarify many febrile phenomena, such as chills, tachycardia and the retention of water, is confirmed by the fact that fever does not follow the puncture of the tuber cinereum in suprarenal-ectomized animals. Besides that, fever determines the temporary disappearance of diabetes insipidus, as a result of the hyperactive functions of the posterior lobe of the hypophysis.

A Study of Total Deafness

Some time ago, Dr. Novak of Prague, director of an institute for deaf and mute patients, published the results of experiments undertaken to establish whether there is absolute deafness or not. He concluded that there is no absolute loss of the hearing power. Similar experiments were carried on in Rumania by Dr. Koleszár, who, like Novak, chiefly used radio amplifiers. His experiments revealed that the majority of deaf people are still sensitive to several tones. The limit of oscillations to which the deaf are yet sensitive is between 128 and 1,024. It was also revealed that if deaf persons hear music or singing, with adequate amplifying, they are able to hear only pure tones. They clearly hear only the pure basal tones and those between certain limits. This explains why they are unable to distinguish between the tones of a violin and of a clarinet. When listening to a band, they feel as if only one instrument were playing. This is true in regard to speaking tones. If deaf persons hear something in a talk at all, they hear wholly different tones than a normal person. They hear better the deep tones. Soprano voices they do not notice at all. Certain consonants they do not hear at all. Thorough investigations show it possible exactly to know what hearing power remains. The greatest achievement of the investigation is establishment of the fact that there is no total human deafness toward every tone as long as the hearing organ is not fully destroyed.

Proposed Radical Changes in the Public Health Service

Costinescu, minister of public health, has proposed the adoption of a regulation intended to encourage young physicians to settle in villages where there is a great scarcity of able practitioners. The state would guarantee to such new physicians 2,000 lei (\$20) a month. The ministerial council has approved the idea but finds that the plan cannot be enforced by a regulation, so it has instructed the minister to draft a law, to be placed shortly before the national assembly.

The ministerial council wishes to alter this plan by a radical change in the public health service. According to its plan, every public health service, state or private, should be under the direction and control of the ministry of health. All county and municipal hospitals would come into the sphere of action of the ministry. Health institutes (social insurance, pay offices) would carry on their administration autonomically, but the medical staff would be under the control of the ministry.

Marriages

RALPH HAYES HOFER, P. A. S., Lieut., U. S. Navy, to Miss Emily Louise Lawrence of Portsmouth, Va., in San Diego, Calif., December 1.

ZELMA ROWENA MACKIN McMANUS, Tyro, Kan., to Mr. Ian Sinclair Mackillop of Detroit at Independence, recently.

CHARLES THOMAS BROWN, San Marcos, Texas, to Mrs. Katie Belle Le Wrage of San Antonio, December 8.

CHESTER B. THRIFT, Rapid River, Mich., to Miss Mildred Russell at Bay City, November 4.

FRANK E. WHITACRE, Chicago, to Miss Lillian Myers of Sylvania, Ohio, November 21.

HARLEY J. GUNDERSON to Mrs. Winifred Coe Dix, both of Los Angeles, November 25.

Deaths

Harmon Smith, New York; Bellevue Hospital Medical College, New York, 1897; member of the American Laryngological, Rhinological and Otolological Society; past president of the American Laryngological Association; fellow of the American College of Surgeons; formerly professor of clinical surgery (laryngology and rhinology), Cornell University Medical College; surgeon and director of the throat department, Manhattan Eye, Ear and Throat Hospital; consulting laryngologist to the Memorial Hospital and Babies' Hospital, New York; consulting throat surgeon to the Muhlenburg Hospital, Plainfield, N. J., and consulting otologist to the Monmouth Memorial Hospital, Long Branch, N. J.; aged 62; was found dead, December 11, of a wound in the chest, presumably self inflicted.

Andrew Buchanan Small, Dallas, Texas; Memphis (Tenn.) Hospital Medical College, 1888; member of the House of Delegates of the American Medical Association from 1915 to 1916; member and formerly councilor of the fourteenth district of the State Medical Association of Texas; fellow of the American College of Surgeons; professor of clinical surgery, Baylor University College of Medicine since 1915; professor of principles of surgery, Southern Methodist University Medical Department, 1909-1914; senior associate surgeon to the Baylor Hospital and Dispensary; aged 71; died, November 29, of coronary occlusion.

William Webster, Winnipeg, Manit., Canada; Manitoba Medical College, Winnipeg, 1895; associate professor of clinical surgery and anesthesia at his alma mater; member of the Associated Anesthetists of the United States and Canada; served during the World War; author of "Science and Art of Anesthesia" and "Anesthesia for Nurses"; aged 69; for many years anesthetist to the Winnipeg General Hospital, where he died, October 23, as a result of inhaling fumes while extinguishing a fire in his boat.

Herbert Henry Sharpe © Lieut. Colonel, M. C., U. S. Army, Manila, P. I.; Long Island College Hospital, Brooklyn, 1906; entered the medical corps of the U. S. Army as a first lieutenant in 1911 and rose through the various grades to that of lieutenant colonel in 1931; served during the World War; aged 51; for two years stationed at the Sternberg General Hospital, where he died, November 6, of coronary occlusion and arteriosclerosis.

Harvey Mitchell Righter © Philadelphia; Jefferson Medical College of Philadelphia, 1896; also a dentist; demonstrator of clinical surgery at his alma mater; served during the World War; aged 62; on the staff of the Philadelphia General Hospital and of the Jefferson Hospital, where he died, November 24, of pneumonia.

Leo Pecci Bell, Sacramento, Calif.; Harvard University Medical School, Boston, 1915; member of the California Medical Association; fellow of the American College of Surgeons; served during the World War; formerly on the staff of the Woodland (Calif.) Clinic Hospital; aged 43; died, October 4.

Henry S. Ward, Springfield, Vt.; University of Vermont College of Medicine, Burlington, 1887; member of the Vermont State Medical Society and the Associated Anesthetists of the United States and Canada; on the staff of the Springfield Hospital; aged 69; died, September 13, of coronary thrombosis.

John Aaron Kendrick, Greenville, Ala.; Tulane University of Louisiana Medical Department, New Orleans, 1894; member of the Medical Association of the State of Alabama; past presi-

dent of the Butler County Medical Society; on the staff of the Stabler Infirmary; aged 62; died in November.

Martin Otis Heckard © Chicago; Bellevue Hospital Medical College, New York, 1893; for many years registrar of the bureau of vital statistics, city health department; aged 71; died, November 23, in the Illinois Masonic Hospital, of myocarditis and hypertrophy of the prostate.

William Lee Stubbs, Dutton, Ala.; University of Alabama Medical Department, Mobile, 1899; member of the Medical Association of the State of Alabama; president of the Jackson County Medical Society; aged 61; was found dead, November 26, of angina pectoris.

George Clarence Parcher © Saugus, Mass.; College of Physicians and Surgeons, Baltimore, 1893; served during the World War; for many years on the staffs of the Union and Lynn hospitals, Lynn; aged 63; died, November 29, in the Palmer Memorial Hospital, Boston.

Solis-Cohen Bogh Hertzog © Reading, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1923; formerly superintendent of the Berks County Tuberculosis Sanatorium; aged 39; on the staff of St. Joseph's Hospital, where he died, November 6, of pneumonia.

J. Louis Simpson, Brooklyn; Fordham University School of Medicine, New York, 1918; member of the Medical Society of the State of New York; on the staffs of the Coney Island, Kings County and St. Mary's hospitals; aged 45; died suddenly, November 7, of heart disease.

Clarence Anson Neighbors, Anaheim, Calif.; Kansas City (Mo.) Medical College, 1905; member of the California Medical Association and the American Academy of Ophthalmology and Oto-Laryngology; aged 54; died, November 14, in St. Vincent's Hospital, Los Angeles.

Philip Leach © Medical Director, Captain, U. S. Navy, retired, New York; Rush Medical College, Chicago, 1881; entered the navy in 1891 and retired in 1919 on attaining the age of 64; fellow of the American College of Surgeons; aged 78; died, October 19.

Thomas L. Ryan, Saginaw, Mich.; Western University Faculty of Medicine, London, Ont., Canada, 1899; member of the Michigan State Medical Society; formerly on the staff of St. Mary's Hospital; aged 64; died suddenly, August 31, of angina pectoris.

Samuel Davenport Etkin, New York; Long Island College Hospital, Brooklyn, 1908; member of the Medical Society of the State of New York; on the staffs of the Harlem and Mount Sinai hospitals; aged 51; died, November 25, of acute coronary occlusion.

Edwin C. Taylor © Jackson, Mich.; University of Buffalo School of Medicine, 1879; member of the House of Delegates of the American Medical Association in 1923; aged 75; died, November 11, at his winter home in Howey-in-the-Hills, Fla.

John Thomas Rimer, Clarion, Pa.; College of Physicians and Surgeons, Baltimore, 1881; member of the Medical Society of the State of Pennsylvania; past president and secretary of the Clarion County Medical Society; aged 79; died, October 29.

Hugh Mackay, Winnipeg, Manit., Canada; Manitoba Medical College, Winnipeg, 1895; formerly assistant professor of medicine and dermatology at his alma mater; on the staff of the Winnipeg General Hospital; aged 70; died, October 12.

William C. Nordholz © Oak Park, Ill.; Jenner Medical College, Chicago, 1911; served with the American Red Cross during the World War; on the staff of the Garfield Park Hospital; aged 49; died, December 7, of coronary thrombosis.

John Gilbert, Fall River, Mass.; University of Vermont College of Medicine, Burlington, 1886; member of the Massachusetts Medical Society; Civil War veteran; aged 87; died, November 2, of arteriosclerosis and chronic myocarditis.

Howell Lea Castleman © Sylacauga, Ala.; University of the South Medical Department, Sewanee, Tenn., 1901; past president of the Talladega County Medical Society; aged 63; died, November 24, of heart disease, following influenza.

William Zimmermann, Denver; University of Colorado School of Medicine, Denver, 1912; member of the Colorado State Medical Society; aged 56; died, October 5, in St. Luke's Hospital, of cerebral hemorrhage and arteriosclerosis.

Adam Wood Montague, Fort Worth, Texas; Tulane University of Louisiana School of Medicine, New Orleans, 1916; member of the State Medical Association of Texas aged 41; died, November 24, of coronary occlusion.

Burt B. Lamkin © Fresno, Calif.; College of Physicians and Surgeons of San Francisco, 1902; member of the Pacific Coast Oto-Ophthalmological Society; on the staff of the Sample Sanitarium; aged 58; died, October 22.

Albro Joseph Ames, Potter, Neb.; John A. Creighton Medical College, Omaha, 1901; aged 83; died, November 14, in a hospital at Kimball, S. D., of pneumonia resulting from injuries received in an automobile accident.

Cary Carpenter Bradford, Southbridge, Mass.; Harvard University Medical School, Boston, 1882; member of the Massachusetts Medical Society; aged 79; died, October 20, of chronic myocarditis and diabetes mellitus.

Charles Schmidli, Bonfield, Ill.; Reliance Medical College, Chicago, 1910; member of the Illinois State Medical Society; aged 63; died, October 19, in St. Mary's Hospital, Kankakee, of intestinal obstruction.

Charles Everett Carter Peyton, Pulaski, Va.; University of the City of New York Medical Department, 1877; member of the Medical Society of Virginia; aged 79; died, October 30, in a hospital at Roanoke.

Daniel Porter Mixson, Headland, Ala.; Atlanta College of Physicians and Surgeons, 1902; member of the Medical Association of the State of Alabama; aged 54; died, November 9, of cerebral hemorrhage.

William Luther Royster, Indianapolis; Kentucky University Medical Department, Louisville, 1906; served during the World War; aged 51; died, November 24, in the Methodist Hospital, of pneumonia.

William Brooks Turner, Florence, Ala.; University of Nashville Medical Department, 1904; member of the Medical Association of the State of Alabama; aged 56; died, November 28, of pneumonia.

Albert A. Dye, De Funiak Springs, Fla.; Rush Medical College, Chicago, 1871; Civil War veteran; formerly mayor of Madison, Wis.; aged 89; died, November 24, in Asheville, N. C., of carcinoma.

Emily Frances Murphy, Taunton, Mass.; College of Physicians and Surgeons, Boston, 1892; member of the Massachusetts Medical Society; aged 75; died, November 14, of injuries received in a fall.

Charles Edward Park, De Witt, Ark.; St. Louis University School of Medicine, 1903; member of the Arkansas Medical Society; aged 55; died, November 20, in the Baptist Hospital, Memphis, Tenn.

Bernhard F. Bellack, Columbus, Wis.; College of Physicians and Surgeons of Chicago, 1890; on the staff of St. Mary's Hospital; aged 72; died, November 22, of heart disease.

Charles Ober Kepler, Brookline, Mass.; Harvard University Medical School, Boston, 1899; member of the Massachusetts Medical Society; aged 66; died, November 1.

James Halbert Conoly Jr., Gloucester City, N. J.; Temple University School of Medicine, Philadelphia, 1925; aged 36; died, November 21, of pneumonia.

John George Hugo, New Haven, Conn.; College of Physicians and Surgeons, Baltimore, 1903; served during the World War; aged 54; died, November 11.

J. Bennett Millard, Bristol, Va.; Louisville (Ky.) and Hospital Medical College, 1908; aged 48; died, November 4, in a local hospital, of pneumonia.

Ernest Adolphus Sturge, San Mateo, Calif.; University of Pennsylvania School of Medicine, Philadelphia, 1880; aged 78; died, October 12.

Oren A. Chitwood, Fort Worth, Texas; College of Physicians and Surgeons, Baltimore, 1883; aged 77; died, November 6, of angina pectoris.

Francis James Albro Cochran, Toronto, Ont., Canada; Bellevue Hospital Medical College, New York, 1892; aged 69; died, October 23.

Joseph James McVety, Old Town, Maine; College of Physicians and Surgeons, Boston, 1912; aged 47; died, October 31.

Thomas Elbert Rushing, Ramer, Ala.; Medical College of Alabama, Mobile, 1890; aged 68; died, in October, in Eureka, Texas.

Milne Brownlee, Woodstock, Ont., Canada; Faculty of Medicine of Trinity College, Toronto, 1886; died, October 8.

John Cabell Moseley, Henderson, Ky.; Kentucky School of Medicine, Louisville, 1896; aged 59; died, November 15.

Charles H. Matthews, Mount Orab, Ohio; Starling Medical College, Columbus, 1893; aged 72; died, November 8.

William H. Waller, Angola, Ind.; Detroit Medical College, 1874; aged 85; died, November 26, of cholangitis.

Stith T. Hurst, Los Angeles; Rush Medical College, Chicago, 1871; aged 90; died, October 24.

Wilbur N. Morell, Verdale, Minn. (licensed in Minnesota in 1883); aged 77; died, November 10.

Correspondence

THALLIUM NEURITIS

To the Editor:—It seems odd that Cobb and Coggeshall in their extensive and instructive article on neuritis (*THE JOURNAL*, November 24, p. 1608) in listing the chemical causes of neuritis should have overlooked or omitted thallium. This element has been used for the removal of hair in the treatment of tinea capitis, and although its use by dermatologists has been markedly restricted because of the danger of neuritis resulting in blindness or paralysis, the "patent" drug promoters fearlessly entered the field, as exemplified by Koremlu, which bankrupted its backers through numerous lawsuits.

Thallium is also used extensively as a rodenticide (Munch, J. C.; Ginsburg, H. M., and Nixon, C. E.: *The 1932 Thallotoxicosis Outbreak in California*, *THE JOURNAL*, April 29, 1933, p. 1315) and in nonfatal doses may also cause polyneuritis and optic atrophy.

FRANCIS A. ELLIS, M.D., Baltimore.

TRIORTHOCRESYL PHOSPHATE AND POLYNEURITIS

To the Editor:—In a paper on Neuritis by Cobb and Coggeshall in *THE JOURNAL*, November 24, the subject of triorthocresyl phosphate polyneuritis is discussed. The following references are cited by the authors for this type of neuritis on page 1615:

Vonderahe, A. R.: *Pathologic Changes in Paralysis Caused by Drinking Jamaica Ginger*, *Arch. Neurol. & Psychiat.* **25**: 29 (Jan.) 1931.

Merritt, H. H., and Moore, M.: *New England J. Med.* **203**: 4 (July) 1930.

Mella, Hugo: *A Preliminary Report on the Treatment of Paralysis Agitans*, *Arch. Neurol. & Psychiat.* **7**: 137 (Jan.) 1922.

Smith, M. I., and Elvove, Elias: *Pub. Health Rep.* **45**: 1703 (July 25) 1930.

The reference to Mella's paper is obviously an oversight or typographic error, for this report deals with arsenic and not triorthocresyl phosphate, which, so far as I have been able to ascertain, was not known to medical science until 1930.

Neither Vonderahe nor Merritt and Moore make any mention whatever of triorthocresyl phosphate as a possible etiologic factor in "ginger paralysis," and it is very improbable that they knew anything about it. Vonderahe described the pathologic changes in several cases of "ginger paralysis," suggesting a toxin that might reach the peripheral nerves through the circulation and thence travel into the central nervous system along the nerve fibers and anterior roots. The paper of Merritt and Moore merely reports on the clinical aspects of fifteen cases of "ginger paralysis." It is true they suggest some toxic substance, but all they say with regard to it is that "the exact nature of this toxic substance is not known."

The precise etiologic relationship of triorthocresyl phosphate to "ginger paralysis," and its pharmacology, biochemistry and pathology were published in the following series of papers:

Smith, M. I.; Elvove, Elias; Valaer, P. J., Jr.; Frazier, W. H., and Mallory, G. E.: *Pub. Health Rep.* **45**: 1703 (July 25) 1930.

Smith, M. I.; Elvove, Elias, and Frazier, W. H.: *Pub. Health Rep.* **45**: 2509 (Oct. 17) 1930.

Smith, M. I., and Lillie, R. D.: *Histopathology of Triorthocresyl Phosphate Poisoning*, *Arch. Neurol. & Psychiat.* **26**: 976 (Nov.) 1931.

Smith, M. I., and Elvove, Elias: *Pub. Health Rep.* **46**: 1227 (May 22) 1931.

Smith, Engel and Stohlman: *Bull. 160, Nat. Inst. of Health*, 1932.

Smith, M. I.; Lillie, R. D.; Elvove, Elias, and Stohlman, E. F.: *J. Pharmacol. & Exper. Therap.* **49**: 78 (Sept.) 1933.

Smith, M. I., and Stohlman, E. F.: *Pub. Health Rep.* **48**: 734 (June 23) 1933.

Smith, M. I., and Stohlman, E. F.: *J. Pharmacol. & Exper. Therap.* **51**: 217 (June) 1934.

The paper by Harmsma and van Esveld to which the authors refer in connection with "apiol neuritis," which by the way should have been van Itallie, Harmsma and van Esveld, pub-

lished in the *Archiv für experimentelle Pathologie und Pharmacologie* 165:84, 1932, merely confirms the work of the National Institute of Health, showing that a brand of apiol adulterated with triorthocresyl phosphate produced the same type of polyneuritis in several European countries in 1931 as did the ginger beverage similarly adulterated in the United States in 1930.

M. I. SMITH, M.D., Washington, D. C.

Principal Pharmacologist,
National Institute of Health.

FACTORS IN INFANT MORTALITY

To the Editor:—Dr. Levy, in his communication published in THE JOURNAL December 1, in criticism of the article by Drs. Grulee, Herron and myself, stated that "in the presence of such statistical errors, as I have indicated, the case cannot be considered proved." These statistical errors consist of two criticisms.

The first criticism is that we state that the mortality of the group reported was less than one-fourth that of the infant mortality of the same region. This, he says, is incorrect because our group does not contain deaths before 3 weeks of age, whereas the infant mortality of the same region includes all deaths from birth. The infant mortality quoted does not contain deaths occurring in the first two weeks of life. Our only reason in even mentioning these mortalities was to show that our babies were cared for as well as those in the same locality. We are not attempting to compare the results of our controlled group with any "city, state or nation as a whole." What we are trying to show is that, in 20,000 babies, 66 per cent of the total mortality was in 8.5 per cent of the group, which represented the artificially fed babies.

The second criticism is that our group of families contained too many Italian and Russian mothers, and that the infant mortality rate is always lower in babies of these nationalities. In this we heartily agree with Dr. Levy, as their infant mortality rate is lower because the majority of their babies are breast fed, which is exactly what we are trying to show.

HEYWORTH N. SANFORD, M.D., Chicago.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

ABDOMINAL PAIN IN CHILDREN

To the Editor:—When a small child complains slightly of indefinite abdominal pain, with a normal temperature, either no vomiting or possibly vomiting once and the bowels practically normal, with so little tenderness of the abdomen on pressure and so little rigidity of the muscles that they can be scarcely distinguished, what disease is he suffering from, especially when the blood count shows a leukocytosis of from 18,000 to 23,000, with the lymphocytes about 14 per cent and the polymorphonuclears at about 85 to 90 per cent with no urinary symptoms? I have seen several instances of this type and recovery has occurred without operation; but I still think that the condition was acute appendicitis. Are there any other diseases of this character that would give a blood picture like this? In some of these cases it is very difficult to make a diagnosis and I would like to know if there are others who have this difficulty.

J. A. POIRIER, M.D., Forest Lake, Minn.

ANSWER.—The chief symptoms of the small child described in this query are vague abdominal pain with or without vomiting. The chief physical observations are indefinite tenderness and muscular rigidity, and the laboratory examination reveals leukocytosis and increase of the polymorphonuclear elements in the blood. It is stated that there is a normal temperature and that urinary symptoms are absent, though it is not stated whether urinalysis has been done.

Acute appendicitis cannot be ruled out on the information given. In infants and young children the symptoms of appendicitis vary greatly from those which occur in older children

and adults. In infants and young children suffering from acute appendicitis the temperature may be high or it may be normal or even subnormal. Vomiting may or may not occur and, though constipation is the rule, diarrhea may accompany the disease in a certain number of instances. Pyuria may be associated with appendicitis. A polymorphonuclear leukocytosis usually exists. Tenderness over McBurney's point is of great diagnostic importance, if it can be elicited. In young children the appendix frequently lies so deep that the tenderness may be deflected toward the left or upward or it may be entirely absent. Rectal examination in doubtful cases is often extremely helpful, for when palpable resistance on the right side is encountered during this procedure the diagnosis of appendicitis should be strongly suspected. The diagnosis in infants and young children is often extremely difficult and may be confused with intussusception, intestinal obstruction, diffuse peritonitis, pleurisy, pneumonia, gastro-intestinal disturbances, and iliopsoas abscess. In fact, acute appendicitis at this age may be confused with nearly any of the diseases with which infants or young children may be afflicted, because at this age subjective pain is poorly localized and objective signs may be vague or absent. Pain from an earache or sore throat is often referred to the abdominal region by the child, and skill and practice in palpation are necessary to elicit tenderness and muscular rigidity. Any acute infection or infectious disease in a young child may be associated with indefinite abdominal pain and a polymorphonuclear leukocytosis, except those diseases characterized by leukopenia or a leukocytosis of a lymphocytic nature.

PREMATURE OSSEOUS UNION OF SKULL SUTURES

To the Editor:—I have a patient, a baby 10 weeks old, with premature osseous union of the sutures of the skull and of the fontanels. Can and will you give me data on this? Treatment, I suppose, there is none. The infant has the appearance of mental deficiency. The father has had a severe case of diabetes for ten years. M.D., California.

ANSWER.—The condition described is probably microcephalus. It has sometimes been regarded as due to defective bony growth or premature ossification of the skull, but in most cases the early ossification of the skull is usually a consequence of arrested growth of the brain, and not the reverse. A microgyria is present, with agencies of the cortex. The reasons for the developmental arrest of the brain are mostly unknown. If the circumference of the head is much below the average for the age and relatively much less than the measurements of the rest of the body, microcephalus is present. Normally throughout infancy the circumference of the head, chest and abdomen are nearly the same.

The symptoms of microcephalus are those of mental deficiency and often spastic paralysis existing in various combinations and severity. Convulsions often supervene.

As the essential condition in microcephalus is an arrested development of the brain, operative procedures are of no avail. There is no relationship to the parent's diabetes.

RIDGES OF FINGER NAILS

To the Editor:—Will you please tell me if there is any treatment for longitudinal ridges on the finger nails? Please omit name.

M.D., Pennsylvania.

ANSWER.—Longitudinal ridges on the finger nails are mentioned as occurring in gout, and some English physicians maintain that they are diagnostic. This, however, is probably no more true for longitudinal ridges than for transverse furrows or other malformations of the nail, which are caused by a great variety of general or local disorders.

Senility is also a well known cause of longitudinal ridges. Cases have been reported in association with alopecia areata. One observer saw the nail changes occur with two attacks of the scalp disorder, the nails having returned to normal between attacks.

Congenital dystrophy of the nails sometimes takes this form. Crocker mentions this (Crocker, H. R.: Disease of the Skin, ed. 3, Philadelphia, P. Blakiston's Son & Co., 1903, p. 1255) in a boy, aged 12 years, with a central ridge with a parallel groove each side of it on each of his finger nails. The nails were rough, thin and soft. No etiologic factor was found except cold hands. The toenails were normal.

The patient should be thoroughly studied to discover any local or general cause for the nail changes. If this is found, it should be treated. If none is found, pushing the vitamins and protecting the nails against dryness by local applications of ointment of rose water may be tried. Alternating hot and cold baths to stimulate circulation might be of benefit, or even galvanic and faradic electrotherapy.

DIAGNOSIS OF SKIN SENSITIZATION AND
FUNGUS INFECTION

To the Editor:—My sister has had an intractable dermatitis. It began at 15 years of age with involvement of the left index finger. The eruption at that time consisted of exfoliation of the skin; there were no vesicles and no ulceration. The condition would entirely disappear under symptomatic treatment. The patient entered a hospital and trained for nursing at 18 years of age. During this time the condition became worse. The hands, fingers and wrists would scale, leaving small fissures and areas of ulceration, which would heal easily. Later vesiculation set in with intolerable itching and burning. While she was in training, the condition spread to both feet, localized mostly to the skin posterior to the ankle joints over the achilles tendon. She was treated at that time by several dermatologists and received ointments, two series of roentgen treatments, and ultraviolet irradiations with but little relief. Since graduation the condition has been gradually progressing for four years with intervals of quiescence. The patient has been nursing at intervals since graduation and was nursing when the present attack set in. In March 1934 she reported for duty at a hospital and was given one injection of typhoid vaccine, diphtheria inoculation and vaccination for smallpox, which was immediately followed, within three days, by a severe dermatitis, vesiculation followed by ulceration with secondary infection, marked swelling of the wrists and feet, severe itching and burning. The last attack occurred three months ago, followed by gradual improvement. At present the patient is 26 years of age and is married; there are no children. She complains of itching and burning of the hands and feet, loss of weight, sleeplessness and weakness. The husband is well. The family history is negative. The patient has had whooping cough, measles and hay fever. She weighs 109 pounds (49 Kg.) and is 5 feet 2 inches (157.5 cm.) in height. She is restless and depressed. There is a vesicular scaling eruption of the fingers, the wrists, and the posterior aspects of the lower extremity of the legs, the dorsum of the feet at the base of the toes, the plantar aspect of the right great toe and the lateral aspect of the left little toe. Some fissuring, small areas of ulceration, and infection with moderate thickening of the skin have occurred where healing is taking place. Pus has formed in small areas of the feet and about two fingernails. The skin of the remainder of the body is normal. The temperature is 98 F.; pulse, 80; systolic blood pressure, 106; diastolic, 60; hemoglobin, 75 per cent; red cells, 4,050,000; leukocytes, 6,600; small lymphocytes, 8 per cent; large lymphocytes, 12 per cent; polymorphonuclears, 79 per cent; eosinophils, 1 per cent. Blood chemistry reveals nonprotein nitrogen 30, creatinine 1.4, sugar 100. The urine is amber, with a specific gravity of 1.022; it is alkaline, negative for albumin and sugar, and shows a few pus cells microscopically. Treatment at present has consisted of a free diet, calcium chloride intravenously every third day, epinephrine 1 cc. daily, and ointments of oil of cade, procaine hydrochloride and hydrous wool fat. I would appreciate help as to diagnosis and treatment. Please omit name.

M.D., New York.

ANSWER.—Whether the original scaly eruption on the finger was an infection or a local sensitization it is impossible to say, but the case in its later development is evidently a sensitization to one, perhaps several, substances. The recent recurrence was precipitated perhaps by the reaction commonly occurring after injection of typhoid vaccine or the combination of other foreign proteins. A specific sensitization to some one of these foreign proteins may exist. This should be investigated; but the recurrence of the dermatitis can be explained without assuming specific sensitization.

The nature of the vesicles may give some information. If they are very small and easily ruptured, the likelihood of a complicating fungous or bacterial infection is slight. If, as seems probable from the description, they are several millimeters in diameter and rather tough roofed, it is possible that infection complicates the sensitization dermatitis. The roofs of several vesicles should be examined for fungi, and cultures should be made of the vesicle contents on plain and sugar mediums, preferably Sabouraud's maltose agar. To detect food sensitization, the nonallergic diet advised by Rowe may be used, adding one food at a time until, by exacerbation of the eruption, the offending food is found.

An effort must be made, by careful questioning of the patient, by scratch and patch tests with all contact substances, to discover the nature of the sensitization. If this can be done, recovery will be greatly facilitated. If not, general rules of treatment must be followed.

Whether or not a mixed infection is present, the local management may well be begun by painting the vesicular eruption once daily with 1 or 2 per cent potassium permanganate. Before this is begun, a small area should be tested with this medicament for a day to determine whether it irritates the sensitive skin. This rule should be followed with each new local application, particularly those applications which stimulate. If preferred, cool wet dressings of solution of aluminum acetate in from 5 to 20 per cent solution may be used, the dressings made thin so as to facilitate evaporation, and frequently wrung out of the cool solution.

If a fungous infection is present, the next application, after vesiculation has ceased, should be crude coal tar ointment, to which the skin is seldom sensitive. This is spread on thin, removed once a day with oil, and then renewed. A weak

Whitfield ointment may be used, or a lotion of 2 per cent salicylic acid and 2 per cent resorcinol in 50 per cent alcohol may be dabbed on frequently.

A bacterial infection may require the use of stronger bactericides such as ammoniated mercury; but the danger of irritation is much greater with these, and the use of potassium permanganate at the beginning of the treatment will probably eliminate such an infection. When the infection has been subdued, soothing ointments may be used—a thin application of zinc oxide paste or ointment, removed daily with oil, and then the ointment renewed. If the ointment alone does not control the itching, the antipruritics phenol, menthol, camphor or one of the tars may be used in addition to the soothing ointment. As needed, stimulants, the tars, bitumen sulphate, resorcinol or sulphur may be used with caution, after a preliminary test as suggested. As the eruption changes, a corresponding change in local application must be made.

Procaine hydrochloride should not be used. It has no value for external use and may add another to the list of sensitizations already present.

To raise the irritation threshold, the calcium chloride treatment is helpful; but if it has already been used for some time, it had better be discontinued, at least temporarily. If a sensitization to some particular kind of meat has been determined, that, of course, should be interdicted. Other meats should be allowed in moderation. Sodium chloride may well be restricted, particularly if the patient is nervous and requires bromides, which seldom cause skin eruption and are often of great value in the control of sensitization.

In chronic sensitization, even when arsenic or other metallic poisoning cannot be determined, intravenous injections of sodium thiosulphate sometimes are of great benefit. They should be employed, as for arspenamine dermatitis, every day for the small doses, every second or third day for the large doses. Whether they act by raising the threshold of irritation or as a mild shock therapy is not known.

Other forms of shock therapy, intramuscular injections of sterile milk or intravenous typhoid vaccine, should be employed with great caution, if at all, for the reactions are hard to control.

ICTERIC PRURITUS

To the Editor:—A man, aged 70, has a tumor of the right kidney and also one of the gallbladder. The latter is partially obstructing the common duct, causing a mild but intensely itchy jaundice, which has resisted treatment so far. Because of his age and poor cardiorespiratory function, surgeons deem operation inadvisable. However, the patient states that he feels fine except for the itching. Can you suggest any form of treatment, either external or internal? Could you give me any references on the symptomatic treatment of icteric pruritus? Kindly omit name.

M.D., Connecticut.

ANSWER.—General hygienic regulation is of great importance. The diet should be an easily digested one, from which alcohol in all forms and condiments should be excluded. Tobacco should be reduced as much as the comfort of the patient permits.

Hot baths, simple or with sodium bicarbonate, or hot wet compresses may be helpful; but measures should be taken to counteract the drying effect of hot baths. During the bath the skin should not be rubbed. When the patient emerges from the bath, the skin should be partially dried by patting with a towel, and then talcum powder or an ointment such as 10 per cent boric acid in ointment of rose water should be applied. No towel at all may be still better, the water being allowed to evaporate partly, and then the talcum powder applied.

Demulcent baths, if the skin is very dry, may be better. Such a bath is made by boiling two cupfuls of oatmeal in a gauze bag for five minutes, allowing the water to cool, then adding it and the bag to the bath, in which the sodium bicarbonate has already been dissolved. Squeezing the bag forces out the fine particles, which are of value. Soap, and that the mildest, should be used only on the hands, feet and hairy parts.

Locally, calamine lotion made with equal parts of lime water and rose water, or made still less drying by the addition of 5 per cent glycerin, may be used with 0.5 per cent each of menthol and phenol; if it causes chilling, the menthol may be omitted. Camphor chloral may be used in from 2 to 5 per cent strength. If the lotion is too drying, calamine liniment, so called, may be used. It is composed of equal parts of lime water and olive oil, to which calamine powder and zinc oxide are added, 12 per cent of each.

Coal tar solution or alkaline solution of tar may be used in an aqueous solution in 3 per cent strength as a lotion. Alcoholic lotions of 50 per cent strength may be used. They are more cooling but also more drying to the skin.

Though the etiologic factor is impossible to remove, the case is still in a more favorable position than many of the cases of

pruritus in which the etiology is entirely dark. The use of ergotamine tartrate in doses of 0.001 Gm. by mouth three times a day for a few days has given excellent results according to Lichtman (The Therapeutic Response to Ergotamine Tartrate in Pruritus of Hepatic and Renal Origin, *THE JOURNAL*, Nov. 14, 1931, p. 1463). The drug in this dosage seems to be without unpleasant reactions.

The use of hypertonic salt or sugar solution (osmotherapy of Stejskal) intravenously sometimes benefits pruritus by disturbance of the colloidal balance. In this case the sugar may benefit the liver. The urine should be examined for sugar after each injection and, if glycosuria appears, insulin may be given.

Insulin alone in small doses, from 10 to 20 units, is said by several authors to exert an excellent influence in pruritus (Sparks, R. A.: Insulin Therapy of Pruritus, *J. Missouri M. A.* 26:24 [Jan.] 1929).

Sodium thiosulphate intravenously often lessens itching. It may be combined with sugar solution, 1 Gm. dissolved in 10 cc. of sterile distilled water and added to 50 cc. of the 50 per cent sugar solution.

Calcium salts by mouth or intravenously and calcium gluconate by mouth, intramuscularly or intravenously may lessen itching by reducing the irritability of the skin, supposedly by causing thickening of the blood vessel walls.

Blood removed from the patient's vein and immediately re-injected in his gluteal muscles may be of benefit. From 5 to 20 cc. is to be given every fifth day.

Of the older remedies, pilocarpine is highly recommended, given hypodermically with caution in doses of from 0.005 to 0.02 Gm. (one-tenth to one-third grain) once or twice daily, depending on the duration of the effect. Just enough to moisten the skin should be given.

Tincture of cannabis may be tried, from 0.6 to 2 cc. (10 to 30 minims) well diluted after each meal.

EDEMA OF ANKLES

To the Editor—Mrs M. G., aged 36, was seen by me about two months ago, because of edema of the ankles and feet of three years' duration. The edema is worse at night and is entirely relieved if the patient remains in bed for a few days. The past history is negative. The patient had one abortion. She has not undergone any operations or had serious ailments. The husband and one child (18 years old) are both living and well. Menstruation occurs every twenty-eight days, is regular, and lasts for four days. There is no dysmenorrhea. Physical examination is essentially negative. The blood pressure is 120 systolic, 80 diastolic. The ankles and feet appear about one and one-half times the normal size, the edema is more marked on the left. A few superficial varicosities were noted on the legs. Deep veins are patent. Laboratory examination of the urine gave negative results on five tests. The Wassermann reaction was negative. Blood sugar was 100 mg. per hundred cubic centimeters; blood urea, 12 mg. Blood count gave normal results. Hemoglobin was 85 per cent, serum albumin, negative, serum globulin, negative. An electrocardiogram was negative. A roentgenogram of the ankles and feet was negative. Treatment consisted of injection of the superficial varicose veins with 5 per cent sodium morrhuate, resulting in obliteration. The patient was given doses of sodium bicarbonate and potassium citrate, about 600 grains (39 Gm.) of each daily with little improvement. Massage and digitals were also administered. The patient has seen many physicians without relief. Can you suggest a cause of this "idiopathic edema"? Please print initials only. M.D., New York.

ANSWER.—The causes of bilateral edema of the ankles are many. The correspondent seems to have ruled out cardiac and nephrotic edema by the customary tests. It is not obvious from the description whether the onset of the edema was sudden or gradual. Assuming that the deep veins are patent, the patient may still have short clots in the pelvic vessels, which are not infrequent and may manifest themselves in a mild venous insufficiency. The character and atypical course of the superficial varicosities may give a further hint in this direction. A mild lymphedema, as a result of a chronic obliterating lymphangitis, may be present. This edema is usually harder and produces more fibrosis than any other edema. Finally an increased capillary permeability must be considered, which permits the filtration of protein through the vessel wall. The extravascular protein in turn attracts more water and prevents adequate return on the venous side. In younger women, particularly during the summer, ankle edemas are not uncommon and have been explained on such a basis.

Treatment will naturally be based on the proper diagnosis, which may have to be made by a man who has had considerable experience with such edemas. Generally speaking, the patient should sleep with elevated legs at night and put on a light elastic stocking from the toes to the knees before getting up. Thrombophlebitis and lymphedema respond favorably to mild doses (100 roentgens) of x-rays. If a nephritis can be excluded, the treatment may well begin with daily doses of ammonium nitrate, 1 Gm. three times a day, followed on the third day by 1 cc. of salyrgan intravenously.

Protein-leaking capillaries can be reinforced by calcium, which must be given in large doses, preferably a gram of calcium gluconate intravenously and from 5 to 10 Gm. by mouth.

A return of the edema may be expected so long as the actual cause is unknown.

THERMIC SENSITIVENESS

To the Editor.—A man, aged 34, recently came under my care complaining of intense itching and burning of the skin, involving different areas, sometimes the entire body except the face. He has had this trouble since the age of 13, a period of twenty-one years, and has consulted a number of physicians, none of whom could give him any relief. The trouble is present only during hot weather, at which times it is worse when his body is covered with perspiration. Paradoxically, a bath with warm, cold or tepid water leaves his skin burning intensely for about twenty minutes, after which time he feels relieved. He says it is always more noticeable when the wind blows from the south, bringing cool air of high humidity; that a dry, hot north wind makes him feel more comfortable. A slap on the skin makes that part burn at any time. There has never been any eruption or breaking out that he knows of. The past history is essentially negative, there is no history of allergic diseases, and the trouble does not seem to be related to food. Physical examination reveals ringworm between the thighs, about healed, and a spot of ringworm over the sternum. The urine shows no abnormality, and the blood Wassermann reaction is negative. Can you give me any idea as to what this condition is and how it should be treated? Might it be a neurosis? Please omit name. M.D., Texas

ANSWER.—This is apparently a case of thermic sensitiveness.

The therapeutic approach in cases of this type must be varied. The history indicates that the patient is apparently suffering with a combined—hot and cold—sensitiveness. This type of case is extremely hard to manage, and it is necessary to know which tissues are sensitive to heat and which to cold. In some of these cases, heat in one locality may cause reaction and when applied to another may relieve it. The avoidance of undue effort, mental excitement and excessive wearing apparel and the use of fans may ward off an attack in heat sensitive cases. Wetting the hands is sometimes of benefit.

A change in geographic environment is also of benefit, for in this way not only are extremes in temperature avoided but also differences in humidity. Patients whose tissues react locally to heat usually do better in a dry atmosphere than a moist one. If this patient shows a tendency to have a markedly subnormal temperature, the use of desiccated thyroid, insulin or a nonspecific protein therapy may be considered. A higher general average of body temperature is often associated with improvement. The correction of any abnormal body conditions is essential, since these may act as contributory factors. It is remotely possible that the patches of ringworm in this case may be a contributory factor.

Cold sensitive cases usually respond more readily than heat sensitive cases. The use of either hot or cold baths, or their alternate use, may be of benefit. Epinephrine, ephedrine, atropine and sedatives are also of value during the attacks.

DANGERS OF CARBON BLACK

To the Editor.—I have a patient who has worked in the carbon black industry for sixteen months. During the past ten or twelve months he has lost 65 pounds (29.5 Kg.) and is down to his present weight of 135 pounds (61 Kg.). He is 33 years of age and 5 feet 10 inches (178 cm.) in height. I have tried to rule out focal infection and have roentgenographed his chest. The urine is normal. The liver is two fingerbreadths below the costal margin and slightly tender. He complains of general malaise and weakness and some soreness over the right costal margin. He has just come under my observation and doesn't have any fever now but tells me that it has been 101 F. on several occasions and 103 F. one time. He has continued at work until three days ago, when he began his vacation. Please inform me (1) of the hazards of the carbon black industry and the methods of diagnosis, and (2) how the Derrien test for dimethylenol is carried out.

JAMES F. McMURRY, M.D., Sentinel, Okla.

ANSWER.—1. Carbon black is made by burning natural gas in a limited supply of air. Two methods are in use, the channel process and the roller process. In the former the flames of burning gas are caused to impinge on inverted iron channels of various lengths, which move slowly forward and backward. In this process about 1,200 cubic feet of gas is burned to produce one pound of the black pigment. In the roller process the burning gas impinges on slowly revolving steel drums and the black pigment is scraped off as it accumulates. This method requires about 1,700 cubic feet of gas to produce one pound of black pigment. Very rarely carbon black is produced by the burning of artificial gas, producer gas, acetylene gas, and so on. Carbon black is almost 100 per cent pure amorphous carbon. Carbon black should not be confused with lamp black, which may be produced by burning coal tar distillates, kerosene, naphtha, fish and vegetable oils, and the like. In the burning of carbon black the possible health hazards are carbon

monoxide poisoning, carbon dioxide asphyxiation and asphyxiation by the natural gas itself, together with the remote possibility of poisoning by sulphur derivatives and by formaldehyde.

2. Derrien's test is performed as follows: To 10 cc. of the urine to be tested add 1 cc. of 10 per cent sulphuric acid and then 1 cc. of 0.5 per cent sodium nitrite solution. Shake and keep in the dark for five minutes. In another tube (of about 25 cc. capacity) place 2 cc. of freshly prepared 0.5 per cent betanaphthol in ammonia water (21.6 per cent NH_3). Pour treated urine into the betanaphthol solution. Shake and allow to stand for one minute or more. Then add 10 cc. of sulphuric ether. Shake well and cork the test tube, permitting the ethereal solution to separate. After separation, interpretation of the test may be made. If the color of the ether is violet, wine or orange red, the reaction is positive for dinitrophenol. If the ether stratum is colorless or yellow, the test is negative.

PNEUMOTHORAX AND THORACOPLASTY

To the Editor.—1. Have most men discontinued the use of pneumothorax after thoracoplasty? If not, on what grounds has it been given up by some? 2. Is puncture of the pleura at its apex a frequent accident when doing a thoracoplasty? Might it be a serious complication? 3. Would the escape of air, in toto, affect the closing of an apical cavity in which otherwise apparent collapse has been obtained? In other words, does moderate intrapleural tension inhibit coughing, further extensions, bronchial dilatation and bronchorrhea? 4. How soon in the average case will coughing and sputum subside after successful collapse? 5. And if the sputum is positive and a cavity visible, would you regard a thoracoplasty as having failed after a year in the face of improved nutrition and strength? 6. How much crippling and deformity are usually associated with operation on the upper five ribs? Please omit name.

M D., Missouri.

ANSWER.—1. As thoracoplasty is not undertaken in patients in whom artificial pneumothorax can control the condition, it has never been the custom to follow thoracoplasty with a pneumothorax.

2. In a carefully performed operation for artificial pneumothorax, the pleura, as a rule, is not injured. Once in a great while, however, this accident may occur even with the greatest of care. As a rule it is not a serious complication.

3. Moderate intrapleural tension, by which is meant collapse of the lung, might well inhibit coughing. This collapse of the lung, however, should be the result of the thoracoplasty and not of the pneumothorax induced after thoracoplasty. The removal of the intrapleural air is considered by most men an essential step in the operation of thoracoplasty on those patients who have recently had artificial pneumothorax.

4. The subsidence of coughing and sputum depends on so many factors that it is impossible to answer this question with any degree of accuracy.

5. No thoracoplasty can be considered as having resulted in a cure as long as the cavity remains and the sputum is still positive. There are many cases on record in which it has taken more than a year for the sputum to become negative.

6. There should be practically no crippling or deformity, especially when the patient is dressed, after a successful upper stage thoracoplasty.

ARTERIOSCLEROSIS WITH HEMORRHAGES

To the Editor.—Mrs. F. Z. in 1930 (aged 63 then) had an attack of abdominal and thoracic shingles from which she recovered. I saw her in 1930, when she gave a history of having stumbled down stairs some time previously. A few days later she had cloudy vision and tearing. She was confined to her home and to a chair, although she has been able to travel East once. She has high blood pressure, 260 systolic, which has fallen to 200. The urinary examination gave unimportant observations. She is overweight but looks well, eats and sleeps well and has to void urine at least once nightly. Her knees look large but are soft to the touch. Roentgen examination revealed nothing but mild arthritis. She has fallen arches. Neurologic examination by an expert gave negative results. The left tendons were slowed up on my first visit. There are scattered retinal hemorrhages and vision is reduced to 20/200 and unimproved by glasses. Despite all absence of paralysis she says she cannot walk, although she can manage to shuffle for some feet or walk the room, pushing a chair in front of her. She is mentally alert and has always impressed me as having a hardly noticeable scanning of speech. There are no cardiac murmurs, although her pulse is irregular on occasion. She never has had fresh retinal hemorrhages since 1931. What, in your opinion, may be the cause of her inability or unwillingness to walk? Please omit name.

M.D., California.

ANSWER.—It is evident that the patient is suffering from arteriosclerosis, and it seems probable that she has had hemorrhages not only in the retinas but also in the posterior root ganglia as a cause of the "shingles." Under these circumstances it is at least possible that there have been other minute hemorrhages. The fact that the patient can walk when pushing a chair suggests that the difficulty in walking is not due

to loss of muscular power but arises from some defect in equilibration. Nothing is said of dizziness or vertigo, but it seems probable that there is dizziness on assuming the erect posture. The loss of vision is sufficient to give an added sense of insecurity and thus to add an element of fear, which might be regarded as a functional feature. On the whole it seems most probable that there is a combination of disturbance in the vestibular apparatus, possibly the result of hemorrhages, with the element of fear and feeling of insecurity.

SCALENIOTOMY

To the Editor.—Will you kindly give me the technic of scalenotomy as used in the treatment of pulmonary tuberculosis? Please omit name.

M D., District of Columbia.

ANSWER.—Under local anesthesia an incision is made between the sternocleidomastoid and trapezius muscles in a skin crease from 2 to 4 cm above the clavicle, thus exposing the scalenus anticus and medius muscles, with the cervical roots of the brachial plexus between them. The prevertebral fascia is next incised and retracted. While the scalenus anticus muscle is being completely divided at approximately the upper border of the clavicle, the surgeon should carefully protect the subclavian artery, cervical nerve roots and other important structures lying close to the muscle. The cervical roots should then be gently retracted and the broad insertion of the scalenus medius separated from the first rib; the subjacent pleura and one of the roots of the long thoracic nerve, which passes through the substance of the muscle, must be protected. Finally, the surgeon should pass his index finger posteriorly along the first intercostal space and hook and isolate the slender scalenus posticus muscle; this may then be divided with scissors, which are guided by the sense of touch. A review of the anatomy of the field of operation will impress the surgeon with the possibility of accidental operative injury to many important structures during the complete division of the scalene muscles.

INDICATIONS FOR REMOVAL OF APPENDIX

To the Editor.—Will you please inform me as to the safest procedure in caring for a gangrenous appendix, when in the judgment or ability of the surgeon it is deemed wise to leave the appendix in situ. The point I am particularly interested in is, Is it better procedure simply to place a drain or is it wiser to ligate and sever the appendix before inserting the drain? In case the appendix is ligated and left in place, what is likely to happen to it? Does it act in a similar manner to a piece of bowel which is ligated at both ends after being separated from the main bowel?

M D., Chicago

ANSWER.—The gangrenous appendix that has perforated is best removed. The same applies to the ruptured gangrenous appendix if the infection is localized to the immediate vicinity of the appendix, if the appendix can be removed without too much manipulation of the intestine, and if the general condition of the patient permits. If a gangrenous appendix has perforated twelve hours or more before the surgeon sees the patient, and generalized peritonitis is present, it is frequently advisable to delay operation until the infection has localized into an abscess. Such an abscess then can be drained without opening the general peritoneal cavity, and the appendix can be removed six or eight weeks later. Obstruction of the lumen of the appendix, particularly if interference with circulation occurs in the region, usually results in perforation of the appendix.

TRANSILLUMINATION OF TESTICLE

To the Editor.—Kindly discuss the value of transillumination of the testicle as a diagnostic procedure in the determination of sterility. Is it of any value? Is it possible by transillumination to determine atrophy of the testicle? Is it possible in this way to determine the cause of the sterility; that is, whether it is due to mumps or to gonorrhea? Please do not publish my name.

M D., Louisiana.

ANSWER.—The only correct and accurate way to establish the fact of whether the patient is or is not sterile is to collect semen in a condom. This should be examined at once, preferably within thirty minutes after the emission. Transillumination of the testicle as a diagnostic procedure would not appear to have value in this type of case. Mumps is the most frequent cause of atrophy of the testicle. Gonorrhea per se does not affect or involve the testicle. Gonorrhea does involve the epididymis, and in about four out of ten cases occlusion results so that the patient is sterile on the side on which he has epididymitis. Naturally if the patient has had a bilateral attack of epididymitis he stands a four out of ten chance of being sterile. Here again the simple and most accurate way to establish this fact is to examine the ejaculate.

FURUNCULOSIS AMONG WORKERS IN
LEAD-SILVER MINE

To the Editor:—Fully 90 per cent of the employees of a lead-silver mine who work on the lower levels of the mine suffer from furunculosis. The temperature on the levels of the mine is moist and always above 100 F. The lower level is approximately at sea level, while the surface is about 3,500 feet above sea level. Most of these boils are small and seem to start in the hair follicles with or without an abrasion of the skin. Usually they are considered of a minor nature but frequently are completely disabling and constitute a disability of considerable economic importance. Treatment with the ingestion of yeast and the use of furunculosis vaccine has given no results. Changing from the lower levels, where sweating is excessive, to other parts of the mine or surface work shows a gradual amelioration of the condition. Can you suggest any treatment that will permit these men to continue their occupation? Please omit name.

M.D., Idaho.

ANSWER.—The correct treatment is to render the mine more hygienic by air conditioning. The men will be able to accomplish more and will be more healthy. Such an installation in the Robinson Deep Mine near Johannesburg, South Africa, is described in *Science News Letter*, Aug. 18, 1934.

BRONCHIECTASIS

To the Editor:—I have a patient, a man aged 50, suffering with an advanced bronchiectasis of the right lung. There is no sign of tuberculosis, pneumoconiosis, tumor or other conditions in the lungs. It seems to me that he has congenital syphilis, although the blood gave a doubtful Wassermann reaction. I would appreciate your suggestion as to the treatment of this case. Please omit name.

M.D., New York.

ANSWER.—There is really no satisfactory treatment for bronchiectasis. Syphilis and congenital cystic disease of the lung should be ruled out. Congenital syphilis at the age of 50 is extremely improbable.

Medication is of little use and climate is of only occasional value. Surgical treatment, such as collapse or phrenicectomy, is occasionally made use of but is of uncertain value in the ordinary case.

SANITATION OF GARBAGE

To the Editor:—Kindly furnish me with a list of the diseases that could come from the improper disposal of garbage and the dangers of allowing it to accumulate around the home. Please omit name.

M.D., Georgia.

ANSWER.—The accumulation of garbage around the home is objectionable for two reasons: The first is purely an esthetic one: the material is unsightly and will produce bad odors. The second is that garbage may serve as a breeding place for flies. As far as is known, no human diseases are transferred as a result of garbage accumulation. Flies may, of course, convey intestinal diseases such as typhoid when conditions are such that the flies have access to human excreta and to food.

INTRAVENOUS USE OF QUININE

To the Editor:—Can you tell me if there is any marked difference in the action of quinine urea hydrochloride when injected hypodermically than that of other salts of quinine? Does the anesthetic action that follows injection of quinine urea hydrochloride obtain with the other solutions?

WILLIAM A. HINCKLE, M.D., Peoria, Ill.

ANSWER.—There is no essential difference excepting in the degree of irritative action. Anesthesia as well as irritation and ultimate sclerosis follows injection of all the quinine salts.

STERILIZATION OF NEEDLES FOR PNEUMOTHORAX

To the Editor:—How long is it necessary to boil 16 to 18 gage needles to sterilize them for pneumothorax treatments and aspirations? Please omit name.

M.D., New York.

ANSWER.—Boiling 16 to 18 gage needles for ten minutes will safely sterilize them for any purpose.

SAFETY OF NORMAL DELIVERY AFTER
CESAREAN SECTION

To the Editor:—In Queries and Minor notes in *THE JOURNAL*, November 10, page 1470, there is an answer to a query as to the safety of normal delivery after cesarean section. The answer given, while covering many factors, omitted one factor that is probably as important as is the alleged superiority of the lower uterine segment operation; namely, the location of the placental site: if the placental site is anterior, the danger of pregnancy and labor is greater than otherwise.

W. F. HEWITT, M.D., Chicago.

Council on Medical Education
and Hospitals

COMING EXAMINATIONS

ALABAMA: Montgomery, Jan. 7. Sec., Dr. J. N. Baker, 519 Dexter Ave., Montgomery.

AMERICAN BOARD OF DERMATOLOGY AND SYPHILOLOGY: Written (Group B candidates). The examination will be held in various cities throughout the country, April 29. Oral (Group A and Group B candidates). New York, June 10. Sec., Dr. C. Guy Lane, 416 Marlborough St., Boston.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY: Written (Group B candidates). The examination will be held in various cities of the United States and Canada, March 23. Final oral and clinical examination (Group A and Group B candidates). Atlantic City, N. J., June 10-11. Group B application lists close Feb. 23 and Group A application lists close May 10. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh.

AMERICAN BOARD OF OPHTHALMOLOGY: Philadelphia, June 10. Application must be filed at least sixty days prior to date of examination. Sec., Dr. William H. Wilder, 122 S. Michigan Blvd., Chicago.

AMERICAN BOARD OF OTOLARYNGOLOGY: New York, June 8. Sec., Dr. W. P. Wherry, 1500 Medical Arts Bldg., Omaha.

ARIZONA: Phoenix, Jan. 2-3. Sec., Dr. J. H. Patterson, 320 Security Bldg., Phoenix.

CALIFORNIA: Reciprocity. San Francisco, Jan. 16. Regular. Los Angeles, Feb. 4-7. Sec., Dr. Charles B. Pinkham, 420 State Office Building, Sacramento.

COLORADO: Denver, Jan. 18. Sec., Dr. Wm. Whitridge Williams, 422 State Office Bldg., Denver.

CONNECTICUT: Basic Science. New Haven, Feb. 9. Prerequisite to license examination. Address, State Board of Healing Arts, 1895 Yale Station, New Haven.

DISTRICT OF COLUMBIA: Washington, Jan. 14-15. Sec., Commission on Licensure, Dr. W. C. Fowler, 203 District Bldg., Washington.

ILLINOIS: Chicago, Jan. 22-24. Superintendent of Registration, Department of Registration and Education, Mr. Eugene R. Schwartz, Springfield.

IOWA: Des Moines, Jan. 3-5. Dir., Division of Licensure and Registration, Mr. H. W. Grefe, Capitol Bldg., Des Moines.

MINNESOTA: Basic Science. Minneapolis, Jan. 2-3. Sec., Dr. J. Charney McKinley, 126 Millard Hall, University of Minnesota, Minneapolis. Medical. Minneapolis, Jan. 15-17. Sec., Dr. E. J. Engberg, 350 St. Peter St., St. Paul.

NATIONAL BOARD OF MEDICAL EXAMINERS: Parts I and II. The examinations will be held in medical centers where there are five or more candidates, Feb. 13-15. Ex. Sec., Mr. Everett S. Elwood, 225 S. 15th St., Philadelphia.

NEBRASKA: Basic Science. Omaha, Jan. 8-9. Dir., Bureau of Examining Boards, Mrs. Clark Perkins, State House, Lincoln.

NEVADA: Reciprocity. Feb. 4. Sec., Dr. Edward E. Hauser, Carson City.

NEW YORK: Albany, Buffalo, New York and Syracuse, Jan. 28-31. Chief, Professional Examinations Bureau, Mr. Herbert J. Hamilton, Room 315 Education Bldg., Albany.

NORTH DAKOTA: Grand Forks, Jan. 1-4. Sec., Dr. G. M. Williamson, 4½ S. 3d St., Grand Forks.

OREGON: Portland, Jan. 2-4. Sec., Dr. Joseph F. Wood, 509 Selling Bldg., Portland.

PENNSYLVANIA: Philadelphia, Jan. 8-12. Dir., Bureau of Professional Licensing, Mr. W. M. Denison, 400 Education Bldg., Harrisburg.

RHODE ISLAND: Providence, Jan. 3-4. Dir., Public Health Commission, Dr. Lester A. Round, 319 State Office Bldg., Providence.

SOUTH DAKOTA: Pierre, Jan. 15-16. Dir., Division of Medical Licensure, Dr. Park B. Jenkins, Pierre.

VERMONT: BURLINGTON, Feb. 13-15. Sec., Board of Medical Registration, Dr. W. Scott Nay, Underhill.

WASHINGTON: Basic Science. Seattle, Jan. 10-11. Medical. Seattle, Jan. 14-16. Dir., Department of Licenses, Mr. Harry C. Huse, Olympia.

WISCONSIN: Madison, Jan. 8-10. Sec., Dr. Robert E. Flynn, 401 Main St., LaCrosse.

WYOMING: Cheyenne, Feb. 4. Sec., Dr. W. H. Hassel, Capitol Bldg., Cheyenne.

Rhode Island July Examination

Dr. Lester A. Round, director, Public Health Commission, reports the written and practical examination held in Providence, July 5-6, 1934. The examination covered 7 subjects and included 70 questions. An average of 80 per cent was required to pass. Twelve candidates were examined, 11 of whom passed and 1 failed. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
Georgetown University School of Medicine.....	(1933)		89.9
Harvard University Medical School.....	(1932)	88.5,	89.9
Tufts College Medical School.....	(1931)	88.5,	80.9
St. Louis University School of Medicine.....	(1934)		86.9*
Hahnemann Med. College and Hospital of Philadelphia.....	(1933)	89.7,	92.3
Jefferson Medical College of Philadelphia.....	(1934)		88.5*
McGill University Faculty of Medicine.....	(1933)		91.9
University of Montreal Faculty of Medicine.....	(1934)		80

School	FAILED	Year Grad.	Per Cent
Universidade de Lisboa Faculdade de Medicina, Portugal.....	(1932)		74.6

*License withheld pending completion of internship.

South Carolina June Examination

Dr. A. Earle Boozer, secretary, State Board of Medical Examiners, reports the written examination held in Columbia, June 26-28, 1934. The examination covered 17 subjects and included 70 questions. An average of 75 per cent was required to pass. Forty candidates were examined, all of whom passed. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
University of Arkansas School of Medicine.....	(1927)		82.4
University of Michigan Medical School.....	(1934)		90.3
University of Oklahoma School of Medicine.....	(1930)		80.5
Jefferson Medical College of Philadelphia.....	(1934)		83.1
Medical College of the State of South Carolina.....	(1933)		80.9,
(1934) 79.4, 80.5, 80.6, 80.6, 81.3, 81.4, 82.1,			
82.3, 82.4, 82.9, 83.3, 83.5, 84, 84.9, 85, 85, 85,			
85.4, 86.1, 86.3, 86.5, 86.6, 86.8, 87.1, 87.5			
Meharry Medical College.....	(1933)	75, 82.1,	(1934) 80.5
University of Tennessee College			83.9
Vanderbilt University School of "			86.1
Medical College of Virginia.....			84.4, 85.8

Five physicians were licensed by reciprocity from May 2 to July 10. The following schools were represented:

School	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
Birmingham Medical College.....	(1912)		Alabama
Emory University School of Medicine.....	(1923)		Georgia
University of Georgia Medical Department.....	(1900), (1932)		Georgia
Washington University School of Medicine.....	(1929)		N. Carolina

Virginia June Examination

Dr. J. W. Preston, secretary, Board of Medical Examiners, reports the written examination held in Richmond, June 20-22, 1934. The examination covered 9 subjects and included 90 questions. An average of 75 per cent was required to pass. One hundred and twenty-five candidates were examined, 122 of whom passed and 3 failed. The following schools were represented:

School	PASSED	Year Grad.	Number Passed
George Washington University School of Medicine.....	(1933)		1
Georgetown University School of Medicine.....	(1933)		1
Howard University College of Medicine.....	(1933, 4), (1934)		5
Emory University School of Medicine.....	(1934)		1
Eclectic Medical College, Ohio.....	(1927)		1
University of Pennsylvania School of Medicine.....	(1934)		1
Medical College of Virginia.....	(1933), (1934, 59)		60
Univ. of Virginia Dept. of Med.....	(1930), (1933), (1934, 48)		50
Osteopaths			2

School	FAILED	Year Grad.	Number Failed
Howard University College of Medicine.....	(1932), (1934)		2
Medical College of Virginia	(1934)		1

Eighteen physicians were licensed by reciprocity and 1 physician was licensed by endorsement from January 12 to August 15. The following schools were represented:

School	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
George Washington University School of Medicine.....	(1931) Dist. Colum.,		
(1932) Maryland			
Georgetown University School of Medicine..	(1928), (1931) Dist. Colum.,

Tennessee March Examination

Dr. H. W. Qualls, secretary, Tennessee State Board of Medical Examiners, reports the written examination held in Memphis, March 26-27, 1934. The examination covered 8 subjects and included 80 questions. An average of 75 per cent was required to pass. Twenty-four candidates were examined, all of whom passed. The following schools were represented:

School	PASSED	Year Grad.	Number Passed
Howard University College of Medicine.....	(1931, 2)		2
Tulane University of Louisiana School of Medicine..	(1932)		1
Harvard University Medical School.....	(1929)		1
University of Tennessee College of Medicine.....	(1934, 20)		20

Book Notices

Electrocardiography. By Chauncey C. Maher, B.S., M.D., Assistant Professor of Medicine, Northwestern University and the Montgomery Ward Medical Clinics. Cloth. Price, \$4. Pp. 250, with 145 illustrations. Baltimore: William Wood & Company, 1934.

This is "a treatise on electrocardiography, for use by the general practitioner, the medical student, and the specialist exclusive of the cardiologist." There is only one reference to significant literature; "extensive bibliography may be readily found elsewhere." Certain statements are contrary to the experience of other clinicians and at variance with the commonly accepted views in this field of research. "Rheumatic mitral stenosis does not occur in the heart with syphilitic aortitis." "The rhythm" in paroxysmal auricular tachycardia "is strikingly regular . . . This point may successfully differentiate it from auricular flutter, simple sinus tachycardia, or ventricular flutter. Auricular flutter usually occurs as a paroxysm of tachycardia. . . . The chronic form is uncommon." Apparently the author does not consider circus movement the mechanism underlying auricular flutter and fibrillation of the auricles and ventricles. "The mechanism of auricular flutter is relatively simple. . . . The sino-auricular node has lost its rôle as pacemaker to a focus in the auricular musculature . . . This ectopic focus emits stimuli to contraction at a rate of 300 to 400 per minute. . . . In auricular fibrillation, the site of impulse initiation has left the sinus node and is replaced by multiple foci in the auricular musculature . . . Each single focus sends out stimuli at a rapid rate as in . . . auricular flutter. . . . These foci cause localized contraction waves of the auricular muscle which interfere with one another. . . . In auricular fibrillation, in the auricles, there are multiple foci, each rhythmically issuing stimuli constantly interfering with one another." Regarding the mechanism responsible for ventricular fibrillation, he states that "numerous ectopic foci in the ventricles emit stimuli." Ventricular flutter, according to Lewis, is "a condition at present undefined." According to the author, "this mechanism has been termed ventricular tachycardia, which is really a misnomer. . . . Ventricular tachycardia or more technically ventricular flutter . . . Ventricular flutter is essentially a regular succession of extrasystoles arising from an ectopic focus in the ventricular muscle." The diagram illustrating the condition is typical of graphs authoritatively accepted as representing paroxysmal ventricular tachycardia. The fact that the level in the auriculo-ventricular node from which impulses arise alters the relationship of the P wave to the QRS complex is not mentioned. Perhaps, as a result, a condition is described as "a permanent mechanism known as Ectopic Auricular Rhythm in contradistinction to the paroxysmal type, which is much faster." The figure and electrocardiogram presented represent a nodal rhythm arising from the upper portion of the auriculoventricular node; duplicates, so interpreted, have been published by Lewis. These and other questionable or loosely worded statements tend to confuse the beginner having access to other sources of information. This is unfortunate, since diagrams and electrocardiograms, well prepared and carefully selected as are most of these, serve as a valuable aid to the novice. Chapter 8, on axis deviation, is especially well presented. Perhaps this and chapter 12, on the routine interpretation of electrocardiograms, could have been introduced earlier in this presentation.

Problèmes actuels de pathologie médicale. Par A. Clerc, professeur à la Faculté de médecine de Paris, et autres. Troisième série. Cours complémentaire de la Faculté de médecine. Papier. Price, 45 francs. Pp. 339, with illustrations. Paris: Masson & Cie, 1934.

This is the third of the series dealing with pathologic changes in the various medical conditions. The series is edited by Professor Clerc with the assistance of eleven contributors. The subjects discussed are cardiac investigations during the course of diabetes mellitus; disturbed rhythm of the heart in acute infectious myocarditis; parotid sinus; polymorphism and changes produced by Trichocephalus and in Lambliia organisms; delayed hereditary syphilis; hematemesia of splenic origin; primary benign inflammatory purpuras; malignant forms of complete arrhythmias; gastric syphilis; cardiac rhythm with pulsus trigeminus; pulmonary complications in grip, and acute

hepatonephritis. The authors discuss these subjects from the pathologic-physiologic standpoints and interpret the clinical changes on these bases. All the subjects are of interest.

Paul Chevalier, who has written the chapter on purpura, has gotten away from the conventional classification and textbook description of this disease and bases the treatment of the subject on his clinical experience and evidence he has obtained from biopsy of purpuric lesions. He concedes that purpura may be a symptom or a disease. In either case the underlying basis for its causation is essentially vascular. He divides purpuras into the simple acute inflammatory purpuras and into the simple chronic types. Under the acute types, the rheumatoid type occupies most of the discussion. He takes up the various types of syndromes that may be seen under this heading; for example, the joint, abdominal, renal and cutaneous manifestations. He discusses the opinions of various authors in regard to the pathogenesis of purpura but concludes that their facts are inconclusive when attempting to explain clinical forms. Under the discussion of pathology of purpura he offers histologic proof for the inflammatory nature of the purpuric lesion. In both acute and chronic types he finds abundant perivascular infiltration. Under the heading of "chronic purpura" he describes hemogenia as an endothelial plasmatic dyscrasia; in other words, the association of a capillary fragility with a humoral disturbance without local perivascular inflammatory changes. This is undoubtedly comparable to essential thrombocytopenia (Werlhof's disease). He cautions that in many instances cases which really belong under the clinical inflammatory purpuras have been erroneously put into this group. While the author's discussion differs materially from the conventional treatment of the subject of purpura, it is stimulating and contains enough clinical evidence to justify serious consideration.

Mental Defect. By Lionel S. Penrose, M.A., M.D., Research Medical Officer, Royal Eastern Counties Institution, Colchester. Cloth. Price, \$2.50. Pp. 205, with 9 illustrations. New York: Farrar & Rinehart, Inc., 1934.

It has been several years since the publication of the previous good book on mental deficiency. Several monumental works have come out in new editions, but the present volume is the first work that incorporates many of the newer ideas on the subject. Its point of view is somewhat different from that of previous works in that it stresses the general considerations of feeble-mindedness rather than specific types, such as mongolism and cretinism. Its contents can be roughly divided into four parts. The first five chapters contain a short summary of the history of mental abnormality, and systematic investigation, such as the physical examination, physical measurements, laboratory observations and the psychologic examination. The next two chapters discuss the methods of collecting facts from the history and the methods of dealing with these facts. The eighth chapter is an excellent discussion of classification—a subject that is never in a static state. The author is willing to present the various classifications and give some discussion of the merits of each. With the exception of the last chapters, the remainder of the book deals with pathologic types. Mongolism, birth injury and cerebral inflammation are stressed. Although the subject of feeble-mindedness is one of great significance in criminology, the matter is passed over in a page. Two chapters on treatment are given, one of which is a summary of the results of the White House Conference on the Handicapped Child. Those who have had to work with the feeble-minded will have much to criticize in the individual chapters dealing with their special interests; for example, the chapter on psychologic tests is simply a schedule of a few available tests. The significance of the Binet scale is not stressed, yet it is probably the greatest single step investigators have made available for classifying, studying and treating defective cases. In the chapter on treatment in the United States, the book takes an entirely different point of view. The earlier parts emphasize particularly valuable recent researches, but this chapter is a mere summary of the reports made at the White House conference. This is unfortunate, for medical practitioners would be interested in therapy carried out in this country by Clark, Beaman, Svendsen and others rather than attitudes toward the social care of defectives. These attitudes are important but are given a place in their proper proportion in the general

chapter on treatment. Throughout the book the best authorities are cited and properly annotated. The most serious general criticism that can be made arises from the fact that it is too broad in its treatment of the subject for the amount of space allotted. Chapters dealing with important disease entities are short and offer only a modicum of the knowledge available on that subject. Too, the author must have been delayed in his publication, for in the last few years, particularly in America, many significant additions have been made to our knowledge of the subject of feeble-mindedness. The book can be recommended as an excellent general introduction to the field to which it is devoted, but much criticism will arise from experts on mental defects in America because of its scanty treatment of important subjects. It is insufficiently specific in dealing with pathology, symptomatology and treatment to be valuable as a medical textbook in feeble-mindedness. It must be remembered, too, that the medicolegal considerations are British rather than American.

Nutrition and Diet Therapy: A Textbook of Dietetics. By Fairfax T. Prouditt, Instructor in Nutrition and Diet Therapy, University of Tennessee, College of Medicine & College of Dentistry. Sixth edition. Fabrikoid, Price, \$2.75. Pp. 831, with illustrations. New York: Macmillan Company, 1934.

This completely revised edition, including several new chapters, presents latest methods of teaching the fundamental principles of nutrition in health and disease as approved by the American Dietetic Association and the American League of Nursing Education. The text follows the approved outline of courses in Dietetics for Nurses published by the American Dietetic Association (revised edition, 1933). Normal nutrition is stressed throughout. Pathologic conditions are so described as to give the student nurse a good understanding of the relationship between the physician's diet orders and the symptoms of the patient and laboratory reports on his condition. The revisions in this edition are chiefly the result of extended experience in teaching nutrition and diet in disease to nurses and students of dental hygiene, medicine and dentistry. The laboratory class work includes preliminary lessons on the foods to be prepared, their place in the diet, and substitutes for varying the menu. Part I of the book treats of normal nutrition or foods in health. Part II discusses the planning of hospital and family diets and methods of feeding in normal and abnormal conditions and presents pertinent information on the main classes of foods. Part III is devoted to the use of food in the nutrition of the sick, including physiologic information, symptoms and special diets. Part IV covers the preparation of foods. The appendix includes the usual tables on food composition. This is a valuable textbook and ready reference work for nurses and dietitians.

Clinical Toxicology: Modern Methods in the Diagnosis and Treatment of Poisoning. By Erich Lescchke, Professor of Internal Medicine in the University of Berlin. Incorporating Material on Industrial Poisoning by Franz Koelsch, Director of the Bavarian Institute for Industrial Medicine, and with two Appendices: I. The Prevention and Compensation of Industrial Poisoning. By Franz Koelsch. II. The Detection of Poisoning, Post Mortem. By Karl Melchner, Professor of Forensic Medicine, Innsbruck. Translated by C. P. Stewart, M.Sc., Ph.D., Lecturer in General Biochemistry, University of Edinburgh, and O. Dorrer, Ph.D., Research Assistant to Professor Wieland, Munich. The Gloucester Series. Cloth. Price, \$5. Pp. 346, with 25 illustrations. Baltimore: William Wood & Company, 1934.

Murrell's What to do in Cases of Poisoning. By P. Hamill, M.D., D.Sc., F.R.C.P., Lecturer on Pharmacology and Therapeutics, St. Bartholomew's Hospital Medical College. Fourteenth edition of "What to Do in Cases of Poisoning" by Dr. W. Murrell. Cloth. Price, \$1.50. Pp. 208. New York: Paul B. Hoeber, Inc., 1934.

The English translation of Erich Lescchke's book is welcome, for this work marks a new departure in toxicology. It and Ludwig Popper's "Klinik und Therapie akuter Vergiftungen," which was published about the same time last year, treat toxicology as a clinical subject, the result of experience at the bedside. This gives these books an entirely different aspect from the older textbooks on toxicology, of which Murrell's is a type, that have been written not by clinicians but by pharmacologists.

Murrell's little book, even though it aims at being highly practical, starting as it does with "If sent for to a case of poisoning go at once—the patient's life may depend on your prompt attendance," is yet largely theoretical. One has the feeling that the author has not seen or treated many cases of poisoning and that nearly all of what he has to say is second

hand knowledge, neatly arranged and systematized for the student's benefit and for ready reference in case one has the misfortune of being face to face with a case of poisoning, so that one may at least do no harm. It is written impersonally and leaves one cold.

Leschke's book breathes an entirely different spirit. One feels the throb of the real thing when one reads: "Whoever sat up, through the night, with a case of poisoning, whoever has experienced the excitement and care involved in bringing the patient back to life, whoever has busied himself for hours with artificial respiration, stomach pumps, and injections, whoever has felt the despair of the relatives and his own depression at failure if treatment failed or the joy and gratitude if it succeeded . . ." This book has been written "from the standpoint of the practicing physician for the benefit of the physician," just as Murrell's book has been written by a student for the benefit of the student.

Both books have their place and mission. However, one cannot help realizing that in the direction of "clinical toxicology" lies the road to real advance in the diagnosis and treatment of poisoning in man. It is to be hoped that in the future with such models as Leschke, poisoning will no longer be the "Cinderella in clinical teaching and in the further studies of qualified physicians." With this there will come not only an improvement in the diagnosis of poisoning cases, which according to Zangger is wrong in up to 80 per cent of cases, at least at the beginning, but also a greater efficiency in the therapy, which in all probability is not the best possible one in a still larger proportion of cases.

Franklin Palne Mall: The Story of a Mind. By Florence Rena Sablin. Cloth. Price, \$2.75. Pp. 342, with 8 illustrations. Baltimore: Johns Hopkins Press, 1934.

The writer of this volume worked for twenty years in association with the subject of the sketch. In the development of the biography Mrs. Mall and Dr. W. H. Welch helped greatly, as did also Drs. Simon Flexner and George L. Streeter. Medical men who studied their embryology with Mall at Johns Hopkins will find this book of special interest, but as a biography of a great teacher, written *con amore*, it will be attractive to all. In an appendix there are bibliographies and reproductions of correspondence referred to in the text. There are some minor errors in the names of persons and particularly the confusion of several middle initials which might easily have been avoided, for example, Frank S. Billings and James B. Angell.

The Inheritance of Resistance to Bacterial Infection in Animal Species: A Review of the Published Experimental Data. By A. Bradford Hill. Medical Research Council, Special Report Series, No. 196. Paper. Price, 1s. 3d. Pp. 71, with 2 illustrations. London: His Majesty's Stationery Office, 1934.

This report, prepared under the direction of the Statistical Committee of the Medical Research Council, consists of an able and critical review of the results of the experimental investigations dealing with the problems of inheritance of resistance or immunity to bacterial infection. The difficulties inherent in work of this kind are emphasized. The report will be of service in the planning of further investigations in its field.

Mental Deficiency Nursing (Simplified). By O. P. Napier Pearn. M.R.C.S., L.R.C.P., D.P.M., Deputy Medical Superintendent, Cane Hill Mental Hospital. Cloth. Price, \$2. Pp. 281, with 22 illustrations. Baltimore: William Wood & Company, 1934.

The problem of securing adequate attendants for the feeble-minded seems to be as great in Great Britain as it is in this country. In America a strong back and a weak mind seem in many cases to be adequate qualifications for an attendant for mental defectives. Little effort is made in many institutions to train such people, for it is felt that a few adequately trained supervisors will prevent serious consequences from the insufficient mental equipment of attendants. The present work indicates clearly that little more is expected in England in the way of cerebral equipment than is expected here. It is necessary that two-syllable words be divided by hyphens into their component parts in order that they may be intelligible to the English mental deficiency nurse. The book contains summaries of all of medicine, including nursing and hygiene, and a discussion of mental deficiency. Apparently the potential readers

are expected to give hypodermic injections and perform all the duties of a registered nurse, even though the style in which the book is written indicates their incompetence to do so. For the nurse who is otherwise adequate, several chapters (particularly those on mental deficiency) should be of value, because of the fact that the symptoms and characteristics of mental deficiency are carefully outlined and defined; but the curious mixture of intense simplification and highly technical knowledge which the author brought together makes one wonder for whom the book is really adequate—it is too simple for the real nurse and too technical for the stupid attendant. The chapter on nursing and training of mental defectives is not long and is really only an outline rather than a practical guide; yet it should be a guide if the title of the book is not a misnomer. Since it is the first book of its kind, it undoubtedly will serve the purpose of stimulation; but as far as America is concerned a different book for training attendants for the feeble-minded will need to be written. The chapters on how to study, and questions for review, are suggestive that this is a book for "cramming" rather than for education.

The Technique of Contraception: An Outline. By Eric M. Matsner, M.D. Foreword by Robert L. Dickinson, M.D. Introduction by Foster Kennedy, M.D. Published for the American Birth Control League, Inc. Second edition. Paper. Price, 50 cents. Pp. 38, with 32 illustrations. Baltimore: Williams & Wilkins Company, 1934.

This review of the technic of contraception will probably be in considerable demand, combining as it does, in the space of forty pages, a discussion of many different methods of birth control. The author divides them into practical methods, impractical methods, and methods requiring further experimental and developmental research. Diagrams accompany the article and greatly clarify the directions for the use of various contraceptive methods.

Community Hygiene: A Text Book in the Control of Communicable Diseases. By Laurence B. Chenoweth, A.B., M.D., Professor of Hygiene and Director of the Students' Health Service of the University of Cincinnati, and Whitelaw Reid Morrison, A.M., M.D., Professor of Hygiene and Physical Education, and Director of the Men's Gymnasium in Oberlin College. Cloth. Price, \$2.50. Pp. 317, with 112 illustrations. New York: F. S. Crofts & Company, 1934.

It would seem that there are enough textbooks on community hygiene without adding any more, and yet this volume makes an instant appeal because of the comprehensiveness of its scope, the clarity and conciseness with which the subtopics are handled, and the logical organization. The book is well and profusely illustrated and the chapter bibliographies are particular good. It has a good glossary and an adequate index.

Sex Education: Facts and Attitudes. By Various Contributors. Paper. Price, 25 cents. Pp. 59. New York: Child Study Association of America, 1934.

This pamphlet is a collection of articles by a number of different authors, reprinted from various magazines. It is described in the introduction as a pamphlet addressed to parents and designed to offer "not a ready-made philosophy of sex and sex education, but rather suggestions and guidance to the mature parent in search of his own philosophy." Written as these articles are by experienced specialists, they contain many important suggestions but, unfortunately, are couched in terms that will limit their usefulness to individuals familiar with the thought trends and the terminology of modern psychology and education. For the great mass of parents they will not be of much help, because they are written in terms which only the specialist will be likely to find comprehensible.

The Human Machine: Its Uses and Abuses. By Lorena M. Breed, M.D., F.A.C.P. Cloth. Price, \$1.50. Pp. 101. Boston: The Stratford Company, 1934.

Comparison of the human body with the machine has of late years been regarded by health educators not only as trite but not particularly apropos. The modern concept of the machine as a standardized mechanism with interchangeable, replaceable parts does not convey a happy picture of the human body, which is in no sense standardized, has no replaceable parts, and is subject to influences of a psychic and emotional character that have no place in a machine. However, for those who like the mechanistic conception, this book utilizes it probably to its

best advantage. With so many books available dealing with hygiene, it does not appear that this swift and superficial survey will contribute anything new or valuable. Greatest emphasis is placed on diet. Sanitarians and dietitians alike will deplore the author's apparent insistence on raw milk in preference to pasteurized. A misprint confuses vitamin C with vitamin D in one place, and this might confuse the superficial reader. In general, the hygienic advice given is perfectly sound and yet the book leaves the reader unsatisfied, because it has skimmed too lightly the surface of the subject.

Medicolegal

Autopsy: Consent of Surviving Spouse Bar to Suit by Child.—The defendant company issued two policies of insurance payable in case of the accidental death of Webber, one to his wife and one to his executors, administrators or assigns. Each policy contained a provision reading, in part, as follows:

The Company shall have the right and opportunity . . . to make an autopsy in case of death where it is not forbidden by law.

Webber died under circumstances that made it questionable whether his death was or was not accidental. About a month later, at the instance of an investigator for the defendant, the widow gave written consent to an autopsy of Webber's body. Thereafter the body was disinterred and an autopsy performed over the objection of the plaintiff, an adult daughter of Webber. Alleging that the defendant had no right to disinter the body of her father and to perform an autopsy on it without her consent, she sued the defendant in the United States district court, eastern district, Illinois. A judgment was given for the plaintiff, and the insurance company appealed to the circuit court of appeals, seventh circuit.

Since the policies authorized the insurance company to make an autopsy only "where it is not forbidden by law," the plaintiff contended that the autopsy was not within the terms of the policy because disinterment was unlawful. Smith-Hurd Illinois Revised Statutes, 1933, c. 38, sec. 354, she pointed out, makes it unlawful for anyone *willfully and without authority* to dig up, disinter, remove or convey away from the place of sepulture or interment any human body. This statute, said the circuit court of appeals, is directed against grave robbing or otherwise *willfully and without authority* disinterring a body. With the widow's consent to the autopsy, there was an entire absence of *willfulness* on the part of the insurance company. The court held also that there was "authority" for making the disinterment. While the statute does not indicate the nature of the necessary "authority," it seems to be recognized in Illinois that one may make testamentary disposition of his own body. If one may do this by will, the court could see no lawful objection to one's doing it by contract, as Webber had done. That such an agreement is consonant with public policy is manifested by the fact that such a provision is required by statute to be incorporated in accident policies issued in Illinois. Doubtless an insurance company, if it exercises its right to have an autopsy performed, should arrange for the autopsy within a reasonable time after death, but no question as to the seasonableness of the performance of the autopsy has been presented in this case.

In this case, continued the court, there was specific consent and authorization by the widow and beneficiary, given after the burial, to make the autopsy, which necessarily implied consent to the disinterment. The trend of the authorities is that, apart from testamentary disposition or of special circumstances which may dictate otherwise, a surviving spouse has full authority over the disposition of the deceased as against the next of kin. The court accordingly held that the right to consent to the disinterment and autopsy was vested wholly in the widow and to no extent in the plaintiff, and that the disinterment and autopsy without the consent of decedent's daughter, the plaintiff, gave her no cause of action. The judgment of the trial court in favor of the plaintiff was reversed.—*Aetna Life Ins. Co. v. Lindsay*, 69 F. (2d) 627.

Workmen's Compensation Acts: Perforation of Ulcer of the Stomach.—In the course of his employment, Almuist was required to "pull up and shake out" barberry bushes. Two or more bushes sometimes would be bunched together with a clump of dirt weighing up to 250 pounds, and the workman would then pull the bushes apart by hand or pry them apart with a spade. While so engaged, he collapsed, evidencing distress in the abdomen. His attending physician, on operating, discovered that an ulcer of the stomach had perforated and that the contents of the stomach had emptied into the abdominal cavity. The workman died about six weeks later from "an empyema" due to "pus forming after a complication of perforation" of an ulcer. His widow instituted proceedings under the workmen's compensation act of Iowa. She was denied compensation by a deputy industrial commissioner, whose action was affirmed by the industrial commissioner. On appeal, the district court of Page County reversed the decision of the industrial commissioner and awarded compensation. The employer and his insurance carrier then appealed to the Supreme Court of Iowa.

In denying compensation, the commissioner stated that "the record utterly fails to show . . . there was anything in the nature of accident or incident out of the ordinary." From this statement, said the Supreme Court, it is apparent that the commissioner held as a matter of law that the widow could not receive compensation unless she proved that the injury arose out of an accident or unusual incident. But the compensation act only requires, in effect, that the disability be due to a "personal injury." A "personal injury," continued the court, obviously means an "injury to the body, the impairment of health, or a disease, not excluded by the act, which comes about, not through the natural building up and tearing down of the human body, but because of a traumatic or other hurt or damage to the health or body of an employee. . . . The injury to the human body here contemplated must be something, whether an accident or not, that acts extraneously to the natural processes of nature, and thereby impairs the health, overcomes, injures, interrupts, or destroys some function of the body, or otherwise damages or injures a part or all of the body." In the present case, observed the court, the workman's employment was exceedingly heavy, requiring much lifting, pulling and prying, thereby causing a straining of the stomach. The workman's physician testified that there would have been no perforation had it not been for the strain of the work, and there was no evidence to the contrary. The death in this case, concluded the court, was due to a "personal injury" within the meaning of the compensation act.

However, the court reversed that part of the judgment of the district court which awarded \$318 for medical expenses. Section 1387, Iowa Code, 1931, provides in part as follows: "The employer, if so requested by the employee, or any one for him, or if so ordered by the court or industrial commissioner, shall furnish reasonable surgical, medical, and hospital services, and supplies therefor." Medical services, said the court, are to be paid for by the employer and his insurer only under the terms of the statute. If the terms of the statute have not been met, courts cannot order the payment. Here there was no showing that medical services had been requested of the employer, or that a court or the commissioner had ordered such services. To the extent that these medical expenses were allowed, the Supreme Court modified the judgment of the district court awarding compensation to the widow.—*Almuist v. Shenandoah Nurseries, Inc. (Iowa)*, 254 N. W. 35.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Effects of Desiccated Hog's Stomach in Achlorhydria.—Schiff and Tahl state that the oral administration of single doses of desiccated hog's stomach stimulates the secretion of free hydrochloric acid in normal persons and in patients with hypochlorhydria and apparent achlorhydria. The degree of acid secreted may exceed that produced after the injection of histamine, although in the majority of cases the converse is true with dosages of from 5 to 10 Gm. In genuine achlorhydria and achylia gastrica, no secretion of free hydrochloric acid results. The prolonged administration of desiccated hog's stomach in cases of genuine achlorhydria or achylia gastrica may cause the disappearance of symptoms without the return of free hydrochloric acid. The administration of desiccated hog's stomach is beneficial in cases of achlorhydria and achylia gastrica. This suggests that a common factor is lacking in these two conditions, which factor probably is present in desiccated hog's stomach. Evidently this is not the antianemic factor. In some instances, small doses taken at intervals may be adequate to keep the patient free from symptoms. The authors' results obtained during a study of two years, seven cases of which are reported, indicate that the symptomatology associated with achlorhydria is due not to the achlorhydria alone but to the lack of an unknown substance present in desiccated hog's stomach.

Effect of Ulcer Diet on Dog's Gastric Secretion.—Alley investigated the effects on the gastric secretion in two pouch dogs, of some of the foods in the diets of Jarotski, Sippy and Smithies, with the following results: 1. Cream or milk fed repeatedly produced a continuous secretion, and that on cream was much more prolonged than that on milk, but the peptic power on milk was higher. Alkalis increased the volume and acidity. 2. The volumes of secretion on milk or cream were much greater when given repeatedly as compared to those in one feeding. 3. Egg white and butter produced comparatively small secretions. 4. Cream of wheat stimulated a small secretion of high peptic power and low acidity, which was inhibited entirely when given during the peak of butter secretion. Liquid cream of wheat has the power of neutralizing completely the free acidity and of reducing greatly the total acidity of sham feeding juice. 5. Differences of secretory behavior were noticed

between the glands of the greater curvature and lesser curvature regions in that the foods containing fat produced in the former a secretion greater in volume and longer in duration than in the latter.

Treatment of Nonspecific Ulcerative Colitis with Serum Therapy.—In the opinion of Schwartzman and Winkelstein the etiology of nonspecific ulcerative colitis is not established as yet. Nevertheless, whatever the primary, etiologic micro-organism may be, tissues rendered vulnerable by it may become receptive to the effect of natural bacterial inhabitants of the body. Among the micro-organisms of the stool, one particularly worthy of study along these lines is *Bacillus coli*. Serums were produced that were capable of neutralizing *B. coli* toxin in multiple proportions. Twenty-one patients affected with nonspecific colitis were treated with antitoxin, immune horse serums containing from 35 to 75 "phenomenon-neutralizing" units, from 800 to 1,600 agglutinating and from 8 to 16 precipitating units. Following a control period of two weeks, during which emetine and symptomatic therapy were given, conjunctival and intradermal sensitivity tests were performed. If negative, 0.5 cc., 2 cc. and 5 cc. of serum were administered intramuscularly at intervals of six hours during the first day. If these injections were not followed by severe reactions, intravenous medication was given during the next forty-eight hours. It seems important to give large quantities of the serum in a short space of time, otherwise the antitoxin leaves the blood stream quickly. Because of the possibility of dangerous shock, despite negative sensitivity tests, the following precautions were observed: (1) Epinephrine solution was administered even for slight reactions, (2) divided dosage was employed—from 25 cc. to 100 cc.—until 300 cc. was given, and (3) when the dose exceeded 25 cc. the drip method consuming at least one hour was used. In this group, chills and moderate rises in temperature were encountered only twice. Urticaria (mild to severe) was the rule in from two to nineteen days after exhibition of the serum therapy. In eighteen cases the results were good. In fifteen the improvement was evidenced by an abrupt drop in temperature, reduced number of stools and clinical well being of the patients within from two to six days. In these patients, the stools became formed and, sigmoidoscopically, the ulcerations had disappeared in from two to three weeks. In three other cases the improvement was noted in from one to three weeks. The remaining three cases were considered therapeutic failures. In one of these a perisigmoid abscess developed even though the mucosal ulcers healed. In another case the serum was administered early—on the tenth day of a septic course. A study of the toxin of this patient's *B. coli* revealed an absence of neutralization by the serum used. Ten cases have been followed for from six months to one year. In two of this group there were mild recurrences—one at seven months and one a year after treatment.

Development of Synovial Bursae.—Black investigated the subacromial, the prepatellar and the subcutaneous olecranon bursae of 200 human fetuses by means of gross dissection and also in microscopic preparations. Since neither the subcutaneous olecranon bursa nor the subcutaneous prepatellar bursa was present in fetuses, he believes that it is probable that subcutaneous bursae do not develop before birth. Neither the subfascial

nor the subtendinous prepatellar bursae were present in the fetus, although the region in which the subfascial bursa is located was filled with loose tissue. The latter probably develops before the other prepatellar bursae. The subacromial bursa is present in the fetus. It develops early in the third month from a fairly definite anlage. The incidence of this bursa in the fetal period is not so high as in the adults. It was found to be 72.5 per cent before birth, when other factors may play a part in their formation. The structure and form of the subacromial bursa in the fetus differs from that in the adult. It is more rectangular and does not extend relatively as far either posteriorly or anteriorly.

Bacteriophages in Treatment of Colon Bacillus Septicemia.—MacNeal and his co-workers urge the intravenous use of an asparagin preparation of colon bacteriophage in colon bacillus septicemia. In four of their cases the microbe present in the blood stream was found to be susceptible to lysis by their stock colon bacteriophage. In their fifth case the bacteriologic studies were carried out elsewhere and they did not have opportunity for adequate study of the infecting microbe. The observations suggest that organisms of this group virulent enough to produce septicemia are in general more likely to prove susceptible to bacteriophage than those found in the intestine or in the urinary tract. Whether there is an actual correlation between the virulence of the microbe and its susceptibility to bacteriophage cannot be decided from this evidence alone, but the suggestion is of some interest. It seems wise to begin treatment with a stock bacteriophage as soon as the specific nature of the organism in the blood culture has been recognized. At the same time, the testing of this culture against the bacteriophage and the preparation of a specific bacteriophage by filtration of lysed cultures of the specific microbic strain should be pushed as rapidly as possible in the laboratory, and as soon as such a specific preparation is ready it should be used in place of the stock bacteriophage.

Bacteriophages in Colitis and in Intestinal Fistulas.—MacNeal and his associates also find that the empirical use of preparations of bacteriophage potent against some of the intestinal microbes has been followed by favorable results in patients suffering from chronic colitis of undetermined causation. Because of the evident harmless nature of this therapy, it would appear worthy of trial in this sometimes baffling condition.

Postoperative intestinal fistulas infected with a mixture of intestinal bacteria have been, in two instances, influenced favorably by the use of bacteriophages active against the intestinal bacteria. The therapeutic results are not dramatic. The bacteriophages seem rather to exercise a merely beneficent influence on the course of the essentially chronic ailment.

Effect of Epinephrine on the Sympathectomized Extremity.—Smithwick and his associates show that human blood vessels innervated by the sympathetic nervous system become sensitized to circulating epinephrine following resection of sympathetic ganglions. Tests in a series of nine cases in man following complete sympathetic denervation of extremities have shown marked vasospasm in the presence of minute quantities of epinephrine in the circulating blood. The intravenous infusion of a 1:250,000 solution of epinephrine, an amount which causes little change in the normal extremity, is sufficient to lower the surface temperature of the denervated side as much as 15 degrees F. Similar changes take place when the patient's suprarenals are stimulated to secrete epinephrine by insulin hypoglycemia. Identical vasospastic phenomena, which occur in sympathectomized cats and rabbits in insulin hypoglycemia, are abolished by suprarenal denervation. This hypersensitization of the arteries to epinephrine takes place only on degeneration of the vasomotor nerves. It is not present after procaine hydrochloride block or during the first week after operation. It takes from seven to eight days for sensitization to appear. The authors believe that this hypersensitivity to the circulating hormone epinephrine, which develops in sympathectomized extremities, constitutes a heretofore unrecognized but important source of unsatisfactory results in Raynaud's disease.

Struma Lymphomatosa Associated with Hyperthyroidism.—Polowe reports a case of struma lymphomatosa associated with hyperthyroidism in a woman aged 26. It is shown that clinically the reconstructed sequence of events may be, first, a phase of hyperthyroidism; second, a phase of apparently normal thyroid activity, which may or may not be associated with symptoms referable to compression of the trachea and, third, a hypothyroid or myxedematous phase, which also may or may not be associated with symptoms referable to compression of the trachea. Because of its usually insidious course it is conceivable that struma lymphomatosa may go unnoticed in any of its phases during the life of the patient. It is too soon for the author to judge the efficacy of thyroidectomy during the early stage of struma lymphomatosa associated with hyperthyroidism. Thus far the patient is improved definitely. Thyroidectomy is contraindicated unless the pressure on the trachea interferes greatly with the patient's activities. Joll suggested the administration of dried thyroid as a postoperative therapeutic measure, with regular check ups on the basal metabolic rate as a guide.

*Blindness After Neoarsphenamine: Case. F. Juler.—p. 809.

Effect of Acid Extract of Anterior Pituitary on Thyroid.—Scowen and Spence produced thyroid hyperplasia, exophthalmos and suprarenal enlargement in guinea-pigs by the prolonged administration of acid extract of anterior pituitary substance. Although the majority of the thyroids had involuted to the colloid state during treatment, a certain proportion remained hyperplastic even after ninety-three days. The suprarenal enlargement was greatest in those animals whose thyroids had involuted. No evidence of thyroid exhaustion was observed. The production by Collip and Anderson of an antithyrotropic factor in the serum of an animal treated for a prolonged period with thyrotropic hormone has been confirmed. The mechanism responsible for the thyroid involution is discussed.

Blindness After Neoarsphenamine.—Juler reports the case of a woman, aged 46, having a positive Wassermann reaction who was given six doses of neoarsphenamine, commencing with 0.3 Gm. and concluding with 0.9 Gm. twenty-eight days later. She was also given a mixture of red mercuric iodide by mouth. A skin rash developed on the day after the last injection. Fifteen days later she became rapidly blind in both eyes; the left lost all perception of light and the right vision was reduced to hand movements. Two days later both disks were white, with slightly hazy outlines and the arteries were narrow, with white lines along them. The vision varied but little afterward and two years later she still had no perception of light in the left and bare perception of light in the right eye. The disks were white with hazy edges; some of the vessels were small and some of fair size. Her general condition remained fair at the time of the onset of blindness; she was in a somewhat toxic state, but there was no encephalitis and no meningitis. The rash had subsided. The cerebrospinal fluid was not examined. Glyceryl trinitrate was administered on the day after the onset of the blindness and a few days later sodium thiosulphate was given intravenously, but without benefit. The Wassermann reaction and the Kahn tests were still positive two months later.

Thyrototoxic Hypertension.—Parkinson and Hoyle investigated the common occurrence of thyroid toxemia in patients having essential hypertension (hyperpiesia). They find this association so prevalent and so influential on the course, prognosis and treatment that they submit the term thyrototoxic hypertension as applicable. Without adducing other evidence, the association is sufficiently common to suggest that long standing thyrototoxicosis may be one of the causes of essential hypertension. Such patients are to be separated from the general group of essential hypertension, if not etiologically, then in the sphere of diagnosis and treatment; for the clinical features, course and treatment are largely determined by the coexistent thyroid toxemia. The recognition of this factor must therefore become important in diagnosis. The condition is ten times more frequent in women than in men; it is rare before the age of 40, and most patients are between 50 and 60 years of age. Two thirds have had a chronic goiter for many years, and at least half of these have also manifested chronic thyrotoxicemia. There may be a history of exophthalmic goiter, supposedly cured or even operated on. Thyroid enlargement, usually slight, may be minimal or doubtful; the authors have seen a number of cases in which it has been impossible to demonstrate any enlargement, though the thyroid element could not be denied. In some cases enlargement of the thyroid has been present many years though disregarded or even denied. Yet the tachycardia, thinness or wasting, the thyroid temperament with its energy and restlessness, a fine tremor and other general evidence convinces one of thyroid dysfunction. Moreover, the character of the cardiac enlargement often shows the influence of the goiter in addition to that of hypertension. It determines auricular enlargement; for instance, by way of auricular fibrillation. Sometimes only two or three typical signs of thyrotoxicosis are present, and such cases fall into the group of "masked hyperthyroidism," but here involving hypertension. These combined features in patients with hypertension justify their separation into a clinical group with a distinctive prognosis and treatment. Recognition of the thyroid factor influences treatment. Rational therapy must be discriminating. The question of operation arises for the relief of symptoms and the prevention of auricular fibrillation and consequent cardiac failure. Subtotal thyroidectomy will often relieve symptoms and prevent or dispel auricular fibrillation, which so often determines a premature heart failure in hypertension.

Gastric Lesion Produced by Extract of Pituitary.—Dodds and his associates found that the posterior lobe of the pituitary contains a substance capable of inducing a severe lesion of the acid-bearing area of the stomach. This is efficacious when injected subcutaneously, and it is contained also in the standard British Pharmacopoeia extract of the posterior lobe. This extract is active by mouth. The oxytocic principle even in massive doses will not produce a lesion, while the pressor factor in similar doses has a definite action. Although it would appear that the gastrototoxic factor may be a substance differing from the other two hormones of the posterior lobe, a definite statement cannot be made until it has been further purified. The authors state that at present it is impossible to know whether the substance in smaller quantities plays a physiologic part, nor is it possible to state its mode of action. It seems that either the substance has a direct toxic action on the cells of the acid-secreting area of the stomach or perhaps it stimulates secretion of hydrochloric acid to a damaging extent. They are performing intensive investigations on the chemical nature and mode of action of the compound.

*New Procedure of Functional Examination of Liver: Deaminizing Power of Liver After Glycocol Injection. S. Caccuri and A. Chiariello.—p. 840.

Treatment of Gastroduodenal Ulcer.—Fernandez treated nine patients having duodenal ulcers with the Bazzano method. After examination and diagnosis they received daily intravenous injections of 2 cc. of a 25 per cent aqueous solution of sodium benzoate. At the same time they were kept at rest in bed and given a milk diet at first to which additions were made later. After a series of from twenty-five to thirty injections, treatment was suspended to observe the late effects. Some patients received two or three series. Except for slight arterial hypotension following the penetration of the medicament in the veins, no untoward incidents were observed. The pains, vomiting and epigastric tenderness receded rapidly. Burning, however, sometimes persisted and necessitated the addition of alkalis to the diet. The blood disappeared from the stools, there was a gain in weight, the general condition improved and often the roentgenologic signs disappeared. The author is nevertheless skeptical in attributing the improvement to sodium benzoate.

Functional Examination of Liver.—Caccuri and Chiariello attempted the examination of the functional capacity of the liver by means of the Bufano technic. This consists in the intravenous injection of 10 cc. of a 12 per cent solution of glycocol and measurement of the blood amino nitrogen before and fifteen, twenty, thirty and sixty minutes after the injection. Normally there is a decrease in the amino acid proportion after the injection. If there is a change in hepatic function, this proportion shows an increase, which may persist until after the end of the test, associated with variations depending on the functional state of the liver. After studying this method in normal persons, the authors studied the amino acid in the blood after the injection of glycocol in eighteen patients with hepatic lesions. These were divided as follows: One with common duct stones had icterus, five cirrhosis, one cirrhosis, malaria and syphilis simultaneously, one cancer of the liver, five cholecystitis, one hepatic syphilis, one hepatic abscess, one catarrhal jaundice, one colitis and mild liver enlargement, one a double mitral lesion and aortic insufficiency in a state of decompensation with liver enlargement, one sulphocarbonism, and one syphilis after arsenical treatment. In all these patients the amino acid curve showed the functional state of the liver. The same technic was followed in rabbits intoxicated by phosphorus, carbon bisulphide, trichloro-ethylene and thorium dioxide sol. In all, the amino acid curve gave pathologic results. Finally, in experimental studies on dogs, the amino acid curves following occlusion of the portal vein or bile duct were abnormal, revealing a functional decrease in the capacity of the liver.

Plasma Phosphatase.—Austoni and Coggi studied the phosphatase activity of the blood by the method of Kay in several different bone disorders. Its activity was not found markedly increased except in Paget's disease. In fractures the plasma phosphatase is slightly but inconstantly increased coincident with the solidification of the callus. A definite and constant increase in plasma phosphatase was determined in two cases of intestinal exclusion of bile and obstructive jaundice of ten and twenty days duration, respectively. Similar changes in phos-

phatase could not be determined in icterus of other types. Plasma phosphatase seems closely linked to the metabolism of calcium and phosphorus, and the hyperphosphatemia may be considered an early symptom of changes in the metabolism of these substances.

*New Etiology of Facial Eczema. H. Meister.—p. 993.

Resorption and Elimination of Arsenic.—Leibowitz studied arsenic poisoning in rabbits. He found that following the administration of one large dose (lethal or sublethal) approximately 40 per cent of the poison is eliminated with the urine and 15 per cent in the feces in the course of from five to seven days. The changes in the resorption and elimination of the arsenic that are produced by opiates, particularly by a preparation containing the total opium colloids in the form of soluble hydrochlorides, or by absorbents such as purified siliceous earth or medicinal carbon, are not of fundamental significance. Because of the prolonged contraction of the sphincter of the pyloric antrum resulting from the opium preparation, there is a considerable retardation in the passage of the poison from the stomach into the intestine, and resorption of the poison is thus retarded. Subsequent administration of the opium preparation, however, does not produce this effect. The resorption of the arsenic from the intestine is not inhibited by the opium preparation. On the contrary, because the intestinal peristalsis is retarded, the time during which the toxin can be absorbed is prolonged, and more arsenic can pass from the intestine into the blood stream. The arsenic elimination in the urine is slightly increased by the influence of the opiate, but in the feces it is slightly reduced. Purified siliceous earth is without influence on the mechanism of the gastric passage. In the intestine the siliceous earth more or less binds the arsenic, and thus the resorption is inhibited. The elimination in the urine is somewhat reduced under the influence of siliceous earth, but it is somewhat increased in the feces. The action exerted by the opiate on the resorption and elimination of arsenic is nullified by the simultaneous administration of siliceous earth, because the latter absorbs the active colloids of the opiate.

Facial Eczema.—Meister observed in recent months a peculiar facial disorder that became manifest in the form of conjunctivitis, periocular and perioral eczema and edema. He found that the disorder appeared following the use of beaked flutes that were made out of cocobolo wood. The disorder disappeared within about a week but recurred on renewed contact with the flutes. One of the patients, who was an instructor in flute playing, later developed also a hypersensitivity to another type of tropical wood from which beaked flutes are often made; namely, granadilla wood. He did not become completely free from the symptoms until he avoided contact with these woods. The author describes another case of his own observation and states that a third one was reported to him by another observer. He points out that the beaked flute is becoming more popular again and thinks that, if flutes are used that are made of these woods, facial eczema may become more frequent.

CORRECTION

Scarlet Fever Immunization by Nasal Route.—In the abstract of the paper by Friedman and his associates in THE JOURNAL, December 15, page 1889, the last sentence should read "For children less than 3 years of age they recommend, provisionally, a total of 115,000, and in those more than 3 [years of age], 202,000 skin test doses."
